THE NEUROLOGY OF CERVICAL RIBS*

ARCHIBALD CHURCH, M.D.

Professor of Nervous and Mental Diseases, Northwestern University
Medical School

CHICAGO

Supernumerary cervical ribs, as furnishing the cause of many obscure and some very serious nerve lesions affecting the arm, have not been sufficiently recognized in neurologic literature. It is almost startling that no textbook on nervous diseases makes the slightest detailed mention of cervical ribs in connection with brachial plexus disorders, excepting the English translation of Oppenheim. Even the great handbook of Levandowsky has only a slight reference to cervical ribs, and Chipault's "Surgery of the Nervous System" is devoid of any mention of the subject. Works on surgery and radiography have much more.

The frequency of cervical ribs is much greater than is usually understood. Fischel in Prague, in four years, found cervical ribs in 1 per cent. of all the bodies examined. Their most common location is in conjunction with the seventh cervical vertebra, next in relation to the sixth and seventh, and then to the fifth and fourth in descending order of frequency. They have never been observed attached to the first, second or third.

Historically, the cervical rib has been well represented for more than 150 years. Its first description was by Hunalt in 1740, and it was again fully described by Gruber in 1869. In 1894, Pilling collected seventy-six instances. Its first recognition during life was apparently by Cooper in 1818, and it was first surgically extirpated in 1861 by Coote. Since we have had the use of the roentgen ray it has often been unexpectedly found, and not infrequently the roentgen ray adds proof positive to the clinical diagnosis of cervical ribs, which in a general way can be rather definitely diagnosed from the nervous and vascular symptoms they sometimes produce. The very best paper on the subject of cervical ribs is that of Streissler,¹ who considers the subject from every point of view, giving 297 references and 200 cases.

Somewhat strangely in view of the fact that the female organism is supposed to be more stable and less subject to variation than that of the male, 63 per cent. of the cases of cervical ribs are found in women according to Waiter, while Streissler found 70 per cent. female and 30 per cent. male.

Of course cervical ribs are congenital; but clinical manifestations rarely develop under the age of 10, com-

monly make their appearance between 10 and 30, and occasionally give rise to symptoms which first appear only in the later decades of life.

The supernumerary ribs are bilateral in a little more than half the cases, and when lacking in symmetry or represented only on one side, have a disposition to appear more frequently on the left. Occasionally they show hereditary tendencies or constitute a family marking. Thus, Russell² found them in sisters, Drehmann³ in a family presenting eighteen cases, and I have seen them in a mother and daughter.

The disturbance occasioned by cervical ribs does not bear any definite relation to the size of the rib, some of the largest occasioning no symptoms at all, and some comparatively small ones being attended by very disabling and even destructive processes affecting the upper extremity.

Gruber is disposed to classify cervical ribs, according to their size, into four groups:

1. Consisting only of a node which does not extend beyond the lateral dimensions of the transverse processes of the vertebra.
2. A blunt finger of bone 4 or 5 cm. in length.
3. A rib which extends far enough forward to articulate with the first rib or even to be attached to the sternum by a ligamentous cord.
4. A complete rib having vertebral origin and costosternal cartilage.

These ribs are commonly associated with other skeletal abnormalities, especially those marking the sternum, the vertebrae and the ribs. The articulation of the cervical rib to the vertebra either is in the form of a full synostosis, or in some cases the union is partially osteal. Modifications of the scalene muscles are occasioned by the projection of this adventitious bony development, but the subclavian artery always curves above the rib or the fibrous cord, which extends from the tip of the rib forward to the sternum and which in certain cases causes as much difficulty and as much damage as a thoroughly developed bone.

The thorax is changed in its conformation to some extent, having higher apexes with salient arteries readily palpable above the level of the clavicle; sometimes visible pulsation can be made out in the triangles of the neck. This unusual extent of the pulmonary tissues and the feeling of bony hardness or osteal intumescence is a frequent source of mistaken diagnosis.

ETIOLOGY

The disturbances arising from the presence of cervical ribs, which commonly appear only after the child-

the first decade of life, seem to be brought about by the naturally increasing rigidity of the bony and cartilaginous structures, reduction of elasticity of arteries and nerves, and the increased weight thrown on the upper extremities in the various activities of life. Occasionally the disorder in the arm is induced by traumatism, such as bruises or pressure occurring from carrying heavy weights on the shoulder or in the hands. Frank¹ reports a case in which a yoke used for carrying milk pails brought about disturbance in the arms in the case of a milkmaid who had cervical ribs, and Streissler has seen a case in which carrying a gun on the shoulder led to the development of disorder in the hand. In one of my cases, symptoms followed long continued efforts at cranking a gas engine, and in another, unusual lifting of heavy objects preceded the onset of symptoms.

Tuberculosis affecting the pulmonary apex has of course been found in frequent association with cervical ribs, and in some instances the contiguous inflammation seems to have disturbed the brachial nerve trunks in their passage over this adventitious structure. So pleurisy, exudation, and occasionally the loss of fat,

Fig. 1. Very large right cervical rib, smaller left cervical rib, indicating compensatory curves. Cervical scoliosis with compensatory curves. Not due to local or nervous symptoms.

thereby laying the parts subject to more intimate injury, have led to the development of these peculiar disorders. The fracture of the clavicle and the development of callus, encroaching on the space between the shoulder girdle and the thorax, have been the initial features in some cases. Periostitis of the supernumerary rib has occurred, and occasionally it is the seat of tumor growth. Nerves which are exposed to the disadvantage of passing over an additional rib, under general systemic toxic conditions, such as those associated with diabetes and arthritis, have shown an additional local inflammatory disorder in their peripheral distribution, subsequently followed, so, too, arteriosclerosis of the clavicular arch as a close apposition to the rib. In the case of the supernumerary rib, on a series of fifteen the cervical structure, as well as the vascular distribution, had been noted.

SYMPTOMATOLOGY

As already indicated, the symptomatology is that of the nerve and reaches also to cervical structures.

¹ Frank, C. S. *Ann. Surg.*, 1906, 43, 103. ² Streissler, M. *Arch. Neurol. Psychiat.*, 1906, 1, 103.

relative to the size of the accessory structure. These symptoms consist first of local signs. In some instances a tumor-like mass can be made out at the side of the neck, behind the clavicle, at the apex of the thorax; but the outline of the supernumerary rib cannot probably be ever determined by palpation. A more than usually salient subclavian artery and general widening of the root of the neck and a lofty lung apex are objective in character and capable of detection by the usual means of observation. The roentgen ray furnishes a very definite method of detecting these cervical ribs, but a certain amount of experience is essential in interpreting the plates. Cervical ribs of the first order laid down by Gruber are so clearly parallel with the transverse process that unless the negative is particularly definite and scrutinized with great care, a cervical rib of dimensions which do not carry it beyond the tip of the transverse process may be entirely overlooked. I know of a prominent surgeon who from the roentgenogram determined the presence of a cervical rib which on operation was not found; and subsequent roentgenographic examinations failed to show anything like the artefact which was present in the original negative and which was certainly misleading. Again, when the supernumerary ribs are well developed and tolerably symmetrical, they may be mistaken easily for the first thoracic pair, and it is only by counting the cervical vertebrae and by lateral views that their exact nature can be determined. A rudimentary first dorsal rib has been mistaken for a cervical rib.

VASCULAR CHANGES

While vascular changes are not so common as nerve disturbances, as a rule, in some cases they are very prominent. A change may be found in the character of the pulse as compared with the sound side, and certain positions given the upper extremity may serve to stop the pulse altogether, as, for instance, in the case of a soldier whose pulse failed always when he carried his gun on any part of his shoulder, and equally could be extinguished by raising his hand to the same position. Sometimes by placing the hand above the head or by drawing down on the extremity, as in carrying burdens in the hands, the pulse can be reduced in amplitude and even extinguished. In other cases the pulse will vary with respiration, tending to disappear on full inspiration. In rare cases, disturbances of the subclavian by the pressure of the rib has resulted in thrombosis and loss of all pulse in the extremity. In other cases, aneurysm has formed at the point where the subclavian passes over the rib. Several of these conditions are competent to produce an inequality of the radial beat in the two extremities.

The peripheral circulation in the extremity is very frequently disturbed, and some cases of mis-called Raynaud's disease have been due to cervical rib. The fingers often present a blue, edematous or reddened condition, and this may be accentuated by the involvement of the nerves and the trophic changes and glossy skin that attend a neuritis. Many patients complain that the hand on the affected side is much more influenced by cold, and that the hand is invariably colder than the opposite one. Intense edema, vasomotor flushing, and hyperhidrosis are common in the severe cases.

NERVOUS SYMPTOMS

Nervous symptoms are the most common features in cases of cervical rib that affect the upper extremity. The sensory defect may be confined to the distribution

of a single nerve or may embrace the entire member; and pains of a neuralgic character may radiate to the back of the neck, the back of the shoulder, the neighborhood of the ear, very frequently down the side of the chest in the axillary line, and in some cases are complained of over the entire side of the body. The sensory disturbance is usually most intense in the fingers and most commonly in the ulnar portion of the hand and in the ulnar fingers, although in a fair proportion of the cases the radial distribution in the thumb and index is the seat of the greatest complaint. Paresthesias, hypersensitiveness and hyposensitiveness of all grades may be found in varying cases, and Barker⁵ has from personal experience called very definite attention to dissociation of sensation in the affected member similar to that found in syringomyelia. On the motor side weakness is very common, and if the painful manifestations are pronounced, disuse of the arm leads to a still greater weakness. Very rarely is there complete paralysis. All varieties of claw hand may be encountered, with the corresponding contractures due to the involvement of the roots of the brachial plexus in varying degree or in its entirety. There are commonly functional difficulties in the use of the hand, which sometimes in a minor measure are present only in the finer manipulations, such as writing. These patients usually experience inconvenience and sometimes intense pain when carrying burdens in the hand or on the arm, and frequently adopt a sling that supports the weight of the member and relieves the drag on the injured nerves and vessels at the point of pressure.

TROPHIC DISTURBANCES

Disturbances of the trophic control in the small muscles of the hand and the forearm are very common, and usually the muscle group originating from the internal condyle is the one most involved in the forearm. With this may be found trophic disturbance of the skin, especially at the finger ends, trophic blebs,

Fig. 2.—Bilateral cervical ribs, right one of the first degree, left one of the second degree, according to Garbic. (Courtesy of Dr. Hollis E. Potter.)

glossy skin, changes in the nails, and hemorrhages under the nails. Occasionally the sympathetic nerve has been involved, giving rise to pupillary disturbance, ptosis, and retraction or protrusion of the eye. The phrenic nerve may have been occasionally affected.

5. Barker, L. F.: A Case of Unilateral Circumscribed and Elective Sensory Paralysis, *J. Exper. M.* 1896; *Deutsch. Ztschr. f. Nervenhe.* 8: 348, 1896.

In quite a number of cases, hoarseness is reported. Whether or not the right recurrent nerve which loops under the subclavian at the point where the subclavian arches over the supernumerary rib is ever involved is a somewhat disputed point. Streissler thinks it doubtful. Planet⁶ described a case in which there was hoarseness, and Dr. Carl Davis of Chicago has reported

Fig. 3.—Large asymmetrical cervical ribs, indicated by arrows. Neuritis and vascular disturbances in the right arm. Very slight cervical scoliosis.

two such cases. Weisenstein⁷ reported a case in which a patient was aphonic every morning. This seems to have been hysterical rather than due to involvement of the recurrent. A similar case is reported by Ranzi.⁸ Spiller and Gittings⁹ noted one case in which there was atrophy of the tongue and larynx. I myself have had under observation an otherwise healthy woman who has a symmetrical pair of cervical ribs, and who presents at times paresthesia and numbness in the hands, particularly the right. She has had three very prolonged attacks of aphonia attended by paresis of the right vocal cord. At least two of these attacks have been brought on by overexertion in the way of lifting, and I think, after a faithful search for other causes, are undoubtedly due to involvement of the recurrent by the cervical rib.

CERVICAL SCOLIOSIS AND CERVICAL RIBS

Ever since Garré¹⁰ called definite attention to the presence of cervical ribs, usually asymmetrical or unilateral, in conjunction with cervical scoliosis, the frequency of these observations has been increasing. Streissler found such a scoliosis in 16 per cent. of his cases. Frequently the cervical deviation is attended by more or less asymmetry of the face and of the skull, and of course is attended by compensatory curves in the dorsal region. The deviation of the spine does not always seem to be proportionate to the size of the supernumerary rib; but sometimes a supernumerary wedge-shaped cervical vertebra is found to which the

supernumerary rib is attached. Of course such a scoliosis is attended by some postural displacement of the shoulder and scapula. In every case of cervical scoliosis, supernumerary ribs should be suspected.

DIAGNOSIS

The diagnosis of cervical ribs sometimes is attended with a great deal of difficulty, and a large number of other conditions can easily be confused with them. Tumors in the angles of the neck or growing from the cervical and upper dorsal vertebrae may bring about similar conditions in the related extremity. Aneurysms of the subclavian produce a similar symptom group. Quite a number of cases of Raynaud's disease have been found not to be due to the vascular disorder of symmetrical gangrene, etc., but to have been caused by the vascular and neuritic changes secondary to cervical ribs. As the cervical rib produces a brachial neuritis, its presence has been overlooked in this rather common disorder, the neuritis being attributed to systemic or local conditions of a different order; and so neuralgias affecting the upper extremity have perhaps in many instances been of mistaken origin. Subacromial bursitis and arthritis of the shoulder joint producing painful disability of the upper extremity might easily be confused with the effects of a cervical rib. Several cases have been diagnosed as pachymeningitis cervicalis, others as poliomyelitis, others as progressive atrophy, and still others as syringomyelia. Further, owing to the involvement of the thoracic branches of the cervical plexus, some of these cases have been confounded with intercostal neuralgias, and the cervical scoliosis has for some furnished an acceptable explanation of the changes in the hand, without recognition of its association with and dependence to a large degree on the presence of cervical ribs. Dulness and conformation peculiarities of the lung apex have led to a diagnosis of phthisis, and of course their association, in view of the prevalence of phthisis, is not unusual. If one, however, has in mind the frequency of cervical ribs and their capacity for producing painful vascular and trophic changes and symptoms in the upper extremity, careful search of the case with the aid of the roentgen ray will usually make the diagnosis quite definite.

ROENTGENOGENIC COSTS

Many cases show long periods of symptoms or even of very decided disability, with intervals of comparative or complete freedom. No matter, then, the course of the disorder in the arm is usually protracted and sometimes continues for many years. No matter how well placed at the disadvantage caused by the peculiar anatomic variation presented by cervical ribs, one is easily injured in ordinary life pursuits and may recover under conditions of rest and protection. The rarest instances of numerous severe instances indicate that the tendency

is for the disease to come on insidiously, to advance steadily, and to reach such a degree that amputation of the hand or arm or other heroic surgical intervention is readily accepted. The very severe cases are practically hopelessly short of surgery, which has for its proper object the removal of the cervical rib.

TREATMENT

In the milder cases a conservative treatment is altogether advisable. Rest, avoidance of strain and weight carrying, and the thorough support of the arm by a properly arranged sling all tend to avoid irritation of the nerves and vessels by rib contact. Electricity, massage, applications of heat and cold, and general measures, such as are commonly indicated in a brachial neuritis, have their very definite place in the management of these cases, but in the severer ones give rise to so much pain and inconvenience as to be almost insupportable. In cases of the more pronounced grade, recourse to surgery is the only avenue to cure.

The extirpation of a cervical rib constitutes one of the most difficult of major surgical measures, and must not be lightly undertaken. Not only does it require a

Fig. 4.—Same patient as in Figure 3 after operation for the removal of the right supernumerary cervical rib.

very definite anatomic dissection, but dissection in a very dangerous location that is rendered more dangerous by unusual anatomic relations. A number of surgical mishaps have occurred. Jones¹¹ of Manchester reports injuries to the arteries, to the pleura, and to the subclavian vein. In a number of instances the incomplete removal of the cervical rib has been followed by its regrowth from the proximal stump and the reappearance of all the former disabilities. It seems to be highly important that the periosteum should be completely removed. In other instances, sufficient attention has not been given to the cordlike extension which represents the anterior portion of the incomplete rib, and symptoms have consequently not been relieved. When complete extirpation can be effected, the prospect for full relief and restitution of function is practically perfectly good; but chronic neuritic, vascular and trophic processes, often attended by contractures, require months and sometimes years of time and treatment to recede entirely.

My own experience is based on eleven cases, all of which have been verified either by operation or roentgenoscopy or both, and all of which have been relieved with one exception. In this instance a very competent surgeon removed most of the cervical rib. I must reiterate the view of Miller,¹² who insists that in every case of protracted discomfort, pain, or trophic disturbance in the arm, a careful search should be made for cervical ribs. The same advice applies to every case of cervical scoliosis.

ENCEPHALITIS LETHARGICA*

PAUL WEGEFORTH, M.D.

Captain, M. C., U. S. Army

SAN DIEGO, CALIF.

AND

JAMES R. AYER, M.D.

Captain, M. C., U. S. Army

BOSTON

About the middle of 1917, there was reported by von Economo¹ a number of cases, appearing in Vienna, in apparently epidemic proportions, characterized by somnolence almost simulating sleeping sickness, and ending sometimes after a few weeks or even months in death. The prodromes were headache, nausea and vomiting, suggesting a general infection or intoxication. In addition to these general symptoms, the frequency of the simultaneous involvement of some of the cranial nerves, manifested by ophthalmoplegias, such as ptosis and facial palsy, suggested a localization of the disease in the brain. Examination of the spinal fluid threw very little light on the nature of the disease, the cells in most cases being within normal limits, and repeated bacteriologic examinations yielding no positive results. In addition to the involvement of isolated nuclei of the bulb, there were, in some other instances, other signs of cerebral involvement, such as ataxia and tremor, which suggested disturbance of cerebellar function. Von Economo considered food intoxication as an etiologic factor, but ruled it out by the complete absence of gastro-intestinal disturbances. He also felt that typhoid, influenza and Heine-Medin disease could be excluded, and concluded that he was dealing with a specific disease caused by a living virus resembling, but not identical with, the virus of poliomyelitis. He gave the disease the name "encephalitis lethargica."

Early the following year, March, 1918, Breinl² reported from Australia nine cases of a mysterious disease, the prevalence of which had already been reported from Queensland and New South Wales. His cases were mostly among children, and usually began suddenly with convulsions, high fever, headache and malaise. The patients soon passed into a state of coma lasting from two to three days. The majority of these patients died with hyperpyrexia and respiratory failure. The symptomatology varied exceedingly; the Babinski reflex and Kernig's sign were not constant; the knee jerks were exaggerated in some, and absent in others. Sometimes there was nystagmus, with tremors in the arms and legs. Intestinal disturbances were not uncommon. Spinal fluid obtained by lumbar puncture was negative except for a slight increase in cells. The only symptoms constantly present were the onset with convulsions and high temperature, which were followed by a state of deep unconsciousness; the clinical picture suggested to Breinl an intense irritation of the entire central nervous system. He felt that the spinal fluid findings differentiated the disease from meningitis, the presence of fever from lead poisoning, and the symptomatology from gastro-

intestinal disturbances causing death in convulsions. He concluded that the most important disease from which to differentiate it was poliomyelitis, for he states that in the various reports of poliomyelitis epidemics, there are cases of cerebral or encephalitic type in which drowsiness, deepening into coma, is predominant.

The pathologic picture of Breinl's fatal cases showed lesions that were typical of poliomyelitis—perivascular cell infiltration involving the brain as well as the cord. The gray substance of brain and cord showed a diffuse infiltration with leukocytes and round cells, collected here and there into small foci, around which the gray matter appeared softened. In addition to this the ganglion cells showed changes characteristic of neurophagia. This observer was able to transmit the disease to monkeys by inoculating them with the spinal fluid taken from typical cases. He was further able to transmit the infection from monkey to monkey—the animals showing pathologically the same lesions as seen in the human case. The conclusion was therefore made that the disease was caused by the same virus as that causing poliomyelitis.

About the same time that these observations were being made in Australia, similar cases were under investigation in France and England, and later, reports from Italy and Uruguay³ give evidence that the disease, whatever its nature, was world-wide in its distribution.

In France, where the term "lethargic encephalitis" has found general acceptance, the clinical aspects of the disease have been carefully considered. Netter⁴ regards the disease as a "maladie autonome," the specific agent of which is endowed with an affinity for the nerve centers. He insists that the clinical picture is not that of food intoxication or of a special form of influenza or poliomyelitis. Santoni,⁵ in summing up the situation in regard to the disease, is inclined to regard the malady as a result of localization in the brain of the prevailing influenza. According to this writer, lethargic encephalitis is not identical with poliomyelitis.

In England the disease has received a variety of names, indicating the divergent opinions concerning its identity. During the early days of the epidemic it was felt by many that food intoxication (botulism) was the cause of the manifestations, and such a hypothesis found support in the fact that canned foods, owing to war conditions, were being used extensively. Later the possibility that the disease was a form of poliomyelitis was suggested in numerous reports in the literature. The subject was eventually taken in hand by the government, and a complete investigation into the nature and cause of the disease was completed in 1918 by the Local Government Board on Public Health and Medical Subjects.⁶ According to this report, the work of McIntosh seemed to eliminate botulism in discussion of this disease, for he was unable to show its identity culturally or serologically. Also evidence was brought forward against its similarity to poliomyelitis on clinical (MacNahy), epidemiologic (James), experimental (McIntosh) and pathologic (Marinesco) evidence.

6. Report of Local Government Board, N. S. 121, London, 1918.

Although the disease was thought by many to be a new one, it was not long before the fact became apparent that similar epidemics had been described before, usually associated with the pandemics of influenza. Von Economo, in his original communication, mentioned that similar epidemics had been reported as early as 1712, and similarly in 1891, following pandemics of influenza. Netter also recalls the one of 1891 in France, and mentions that similar cases followed the influenza epidemic of 1895.

Biermer,⁷ in 1865, gives Camerarius credit for having described an epidemic which occurred in Tübingen in 1712. The victims were seized with violent brain symptoms, passing into a prolonged coma; because of the coma the disease received the name of "Schlaf-sucht."

The epidemic of lethargic encephalitis of 1891 originated in the north of Italy. Before much scientific attention was paid to it the lethargy received considerable comment in the lay press throughout Europe. For some unknown reason the disease received the appellation of "nona." The origin of this designation is very obscure, although it is perhaps due to a typographic error in an early newspaper account, and should really be "koma." Whatever its origin or significance, the designation has remained, and the literature of the time is filled with case reports and other references to it. Letters to the *Lancet*⁸ and to the *British Medical Journal*⁹ by their correspondents in Rome during 1890 attributed the circulation of stories concerning the so-called disease to native superstition. On the continent, however, a definite clinical entity was recognized as the basis for the reports, although the exact nature of the disease was never definitely settled. It was considered to have a close relationship to influenza or "la grippe," mainly on account of the almost synchronous appearance of that infection in the districts affected. To support this view it was repeatedly recalled that during influenza epidemics, serious central nervous system involvements are not uncommon, often manifesting themselves in protein symptoms.

In this country, so far as we are aware, the first cases to which attention has been called are those which occurred on the medical service of Major Tasker Howard at Camp Lee, Va., the earliest in November, 1918, and later reported by Gathier.¹⁰ Since then,¹¹

case reports have appeared from Illinois and from Iowa.

The following report is based on personal observation by one of us (P. W.) of five cases at Camp Lee, Petersburg, Va., together with postmortem material from four cases assigned to the other (J. B. A.) for examination by the Army Medical School and the Army Medical Museum.

The first four patients, seen by one of us (P. W.) are evidently convalescent:

CASE 1.—Private A. F., aged 29, white, had had gastrointestinal disturbances since 1911, accompanied by vomiting or acute pain. Jan. 19, 1919, he complained of having double vision, which continued for several days. On admission, Jan. 21, the patient was apprehensive and nervous. His right pupil was larger than the left, and both reacted sluggishly to light and accommodation. The knee jerks on each side were hyperactive. He was thought to have hysteria.

February 7, it was noted that there was a slight weakness of the muscles of the face, in the neighborhood of the left eye and the left corner of the mouth, and when talking the patient spoke from the right side. At this time the spinal fluid contained only 12 cells, and both sugar and albumin

were normal. Eleven days later there were 150 cells present (90 per cent. mononuclears), and the chemical content was normal. Other laboratory examinations were negative. The course of the disease was practically afebrile, and the patient was discharged, March 9.

This patient, at the time of my arrival at the base hospital, was free from all symptoms, but the following still showed clinical signs of the disease:

CASE 2.—Private M. S., aged 28, white, January 20, felt dizzy and weak and had a fainting attack. He felt nauseated but did not vomit. On admission to the hospital five days later, he complained of a feeling of lightness in the head and still had some

nausea. At that time the face was flushed, the throat was congested, and the pulse was accelerated. His temperature was 101. By January 30 (five days after admission), the temperature dropped to normal but showed thereafter an occasional rise, but never exceeded 99.2.

Two weeks later, February 16, the patient was unable to close his right eye, the right pupil was larger than the left, the pupillary reflexes were sluggish, and he was mentally dull. The knee jerks were both very much increased, the Babinski reflex was present, and Kernig's sign was suggestive. The gait was unsteady, and the patient complained of double vision and dizziness. The diplopia passed off in a day, but the paralysis of the facial muscles progressed during the same time so that the entire right side was eventually involved. This palsy gradually cleared up, and when I last saw the patient, March 10, he was practically normal. Examination of the spinal fluid, February 17 (the day when the facial paralysis was at its height), revealed 150 cells (all mononuclears) with normal protein and sugar. The Wassermann test and cultures of the blood and spinal fluid were negative.

CASE 3.—Corporal J. C. K., aged 23, white, with both family and personal histories negative, began to feel dizzy, January 18, and complained of double vision, which persisted

Fig. 1. (Case 6).—Cortical meninges, $\times 66$, arachnoid trabeculae sparsely infiltrated with mononuclear cells and blood globules; pia vessels greatly enlarged.

for two days. This was followed by insomnia, and the patient became nervous and irritable. Examination of the eyes, January 20, revealed vision and extra-ocular movements normal (diplopia had disappeared the day before), but there was some congestion of the retinal veins of the left disk. The dizziness and insomnia persisted, but there was no nausea nor vomiting, and the diplopia did not return.

February 4, the patient's general condition was good, but he still complained of nervousness and a trembling of the lower extremities. He stated also that he felt as if his jaw was going to fall off. The next day he suffered from extreme headache, occipital pains, and soreness over the entire spinal column. Both knee jerks continued to be hyperactive and there was bilateral ankle clonus.

The patient's temperature on admission, January 25, was 100, and it had fluctuated thereafter between 98 and 99.6 until February 20, after which it remained normal.

The spinal fluid, February 1, contained 50 cells and two days later 64. Both times protein and sugar tests were normal. Cultures and Wassermann reaction of the blood and spinal fluid were negative, and a white blood count, taken February 4, was 7,600.

CASE 4.—Private M. H., aged 31, white, had received in October, 1918, a shrapnel wound of the shoulder which was followed by bladder disturbances and partial paraplegia. At the time his present illness began he was doing well and was able to get about with the aid of a cane.

February 16, he began to feel weak, having at times alternate sensations of hot and cold. The following day he remained in bed, but on the 18th, since he had no fever, he was persuaded to sit up. On the 20th, however, his temperature rose to 103 and he had a violent headache, followed by double vision and vertigo, the diplopia lasting twenty-four hours. He complained of drowsiness, but could not sleep well. His throat was very sore. The patient was very apathetic and toxic looking, and the skin was flushed. He was intelligent and well oriented, but was retarded mentally. The extra-ocular movements and pupillary reflexes were normal. The left masseter muscle was definitely weak, but the pterygoids were apparently unaffected. There was slight weakness in the facial muscles around the left angle of the mouth. Otherwise examination of the cranial nerves revealed nothing abnormal. The pharynx was very much injected, and the tonsils were swollen.

There was no stiffness of the neck nor Kernig's sign; the knee jerks were active. The white blood count was 6,000. Cultures and a Wassermann test of the blood and the spinal fluid were negative. The first spinal fluid, taken February 24, was normal and contained 8 cells; three days later the cells had risen to 40 (all mononuclears).

The disease ran a febrile course for a few days after the admission of the patient, but the temperature became normal, March 1. Complete recovery from the acute illness followed.

The four cases so far recounted all went on to recovery. They showed involvement of several of the cranial nerves, notably the oculomotor group and facial, together with symptoms indicating involvement of the long projection tracts to the extremities. The course was mildly febrile and was accompanied in the early stages by headache and nausea. In none of them, however, was lethargy an out-spoken feature.

The three following patients succumbed to the disease:

CASE 5.—Private A. L., aged 22, white, had an attack of sore throat, February 3. Two days later he began to have griping pains through the abdomen which localized in the right ilio-fossa; he felt nauseated and vomited, but had no fever. With a provisional diagnosis of appendicitis, he was under observation on the surgical service. About a week later, after subsidence of these early symptoms, his temperature rose to 102 and his right tonsil became larger and inflamed. He again complained of headache and pain in the abdomen, in addition to which he had considerable dyspnea, respirations, February 9, 10 and 11, reaching from 40 to 60. February 12, the respirations dropped to 30. Three days later he became unconscious and cyanotic, the respirations at this time being shallow, with frequent periods of apnea. All reflexes were absent; the pupils were 5 mm. in diameter and did not react to light. Artificial respiration was used for several hours, during which he would regain consciousness at times and answer questions, and in these periods of consciousness the tendon reflexes were exaggerated. Ophthalmoscopic examination was negative. There was no rigidity of the neck.

The patient died, February 18, the temperature having been normal for the two days that preceded the patient's death.

The urine contained a faint trace of albumin, but otherwise was negative. The leukocyte count, February 6, revealed 7,000, and February 12, 10,700.

The spinal fluid, February 2, 1919, contained 30 cells, (90 per cent. mononuclears). Sugar, albumin, 0. Culture and Wassermann negative.

CASE 6.—Private A. L., aged 24, white, admitted to the base hospital, January 31, complaining that he had not felt well for ten days, had a "swimming in the head" and for a few days previous to admission had felt weak. He was constipated, but there was no headache and his appetite was good. His temperature was 102 and the pulse 88. Physical examination revealed nothing positive except some congestion of the throat and a flushed face.

February 2, the patient became noticeably lethargic and would lapse at times into a muttering delirium. The delirium became aggravated, and restraint was needed to keep him in bed. About this time he was having difficulty in swallowing, and would regurgitate food through the nose. Later he became incontinent. February 6, a left facial paralysis was noted, and the knee jerks were exaggerated. The delirium gradually subsided and lethargy ensued. The patient passed, February 11, into a semicomatose condition from which he could sometimes be roused. The following day the coma deepened and he became cyanotic. He died, February 15, the temperature rising just before death to 107.

Laboratory tests: Blood cultures, February 3 and 4, were negative. Throat cultures for diptheria and hemolytic streptococci were negative. Leukocyte counts were 14,500, February 8, 2,800; February 2, 7,000; February 4, 7,900.

The spinal fluid, February 5, contained 20 cells, 16 mononuclears, 10 per cent.; small mononuclears 50 per cent.; globulin, negative; February 7, 100 cells (large mononuclears 6 per cent.; small mononuclears 94 per cent.); 25 per cent. negative; February 12, 110 cells. Large mononuclears 45 per cent.; small mononuclears, 60 per cent.; globulin, negative. Cultures and the Wassermann test were negative.

CASE 7.—W. F. H., Cuban, white, aged 32, seen in consultation with Dr. W. P. Hoy of Petersburg, Va., and later at Camp Lee, March 11, was an electrician by occupation. The patient had any serious illness before and was the father of three healthy children. January 29, he suddenly became prostrated, felt feverish, and went to bed. His wife did not call in a physician until February 2, six days later. At that time he complained of nausea, and he had vomited several times. There was a marked tremor of both upper and lower extremities, and his temperature was 102. The temperature had dropped in a day to 99, and had not risen above 100 subsequently. February 4, he became very lethargic, associated at first with a low muttering delirium, and for the next five weeks he slept continuously, it being necessary to rouse him to give nourishment. Typhoid fever was suspected, but repeated Widal tests and blood and stool cultures failed to verify the diagnosis. Wassermann tests on the blood were negative.

When I saw the patient, March 11, he was asleep on his side with both arms extended forward. Before the patient was roused, one of the arms was raised; it remained apparently fixed. The other arm was placed in a similar posture; it too continued to hold its position. The muscles of both arms fired in a few seconds and the limbs dropped. Later, when the patient was roused, similar cataplectic phenomena were obtained. After being awakened, the patient was found to be extremely well oriented as to time and place, and answered questions intelligently, though sleepily. Examination of the cranial nerves detected a weakness of the left external rectus. The patient was asked if he saw double, but replied that whereas he had been very much annoyed by the "doubling up" of objects when he was first taken sick, this had passed off in a few days, and at the time of the examination this diplopia was not present. There was a slight droop at the left corner of the mouth, the weakness of the muscles in this neighborhood of being more noticeable when he talked. The tendon reflexes were normal, but the cremasteric and abdominal were hypoaesthetic. After the interview, the patient promptly fell asleep again, and subsequently after being roused sufficiently to assist in getting himself in position for a lumbar puncture, he fell asleep during the operation, which was done without anesthesia. The patient seemed to be improving, for during the last week the lethargy, though still marked, was not so profound as it had formerly been.

I told not only the patient, but also the following notes concerning his illness. On February 29, a count of serum from a cerebrospinal fluid specimen showed 13,600 polymorphonuclears, 83 per cent. On March 1, blood count, 14,600 polymorphonuclears, 74 per cent. On March 3, blood count, 16,000 polymorphonuclears, 74 per cent. On March 5, spinal fluid, no cells; globulin +; sugar —. On March 6, spinal fluid, culture negative; smears revealed no bacteria. On March 12, spinal fluid, no tubercle bacilli. On March 15, spinal fluid, 5 cells; globulin +; sugar —. On March 16, Wassermann test negative. On February 26, blood culture, sterile.

activity was performed, and enough tissue has been removed to say that the lesions are similar in character and distribution to other cases of "lethargic encephalitis."

The following two histories were kindly furnished by the Army Medical Museum when the material for pathologic study was transferred to us:

CASE 8.—Sergeant W. H. E., aged 27, white, admitted to the hospital, Jan. 22, 1919, about noon, complained of headache and seeing double, had been complaining of headache for three or four days, but did not seem sick. At the hospital he walked to the ward, but once in bed he dropped into a drowsy, semicomatose condition from which he could be roused to answer questions, but into which he would immediately return. Examination revealed nothing but fine rales in both chests. Blood culture was negative. He died at 6 o'clock the following morning, January 23, and was said to have had a convulsion before his death.

No history of any drug habit or of recent drinking could be obtained from the man or his friends.

CASE 9.—Private D. S., aged 23, white, a man of good habits, with no significant family or personal history, was taken sick, Jan. 23, 1919, complaining of severe frontal headache and pain in the eyes. He also found that he could not keep his eyes open, and he had been very drowsy since the onset. He was admitted to the hospital, January 25, at which time the only abnormality noted on examination was congestion of the eyes and enlargement of the tonsils. Nevertheless a provisional diagnosis of "acute encephalitis" was made.

During the following week the drowsiness of the patient persisted and there developed signs of organic neurologic disease — sluggish pupillary reflexes and diminished knee jerks and Babinski reflex, external strabismus and signs of meningeal irritability, Kernig's sign and stiffness of the neck, so that a diagnosis of "tuberculous meningitis" was made.

Another week passed in which the drowsiness of the patient deepened to stupor, and twitching of hands and

arms was noted. The week following February 9 the patient seemed better, and would answer questions and smile; the reflexes at this time were found normal, but there was an ocular squint.

Toward the end of February, marked rigidity was noted, and the patient became markedly weaker. At this time the left retina was edematous. He died, March 3. Laboratory data were:

January 25, blood count, 14,600; polymorphonuclears, 83 per cent.

January 26, blood count, 13,600.

January 28, blood count, 16,000; polymorphonuclears, 74 per cent.

February 1, blood count, 15,600.

February 12, spinal fluid, no cells; globulin +.

February 15, spinal fluid, culture negative; smears revealed no bacteria.

February 17, spinal fluid, no tubercle bacilli.

February 26, spinal fluid, 5 cells; globulin +; sugar —.

February 27, Wassermann test negative.

February 26, blood culture, sterile.

Fig. 10 (60x). Meninges, p. 75. The larger shows a mononuclear cell and a portion of its cell body, while the smaller one is more typical.

PATHOLOGIC EXAMINATIONS

Pathologic examination of four cases is given. As all four cases show varying degrees of what appears to be an identical pathologic process, the case presenting the most marked lesions will alone be given in detail:

CASE 6 (Camp Meade, A:115).—Death occurred suppo-cilly five days after the onset of symptoms. Necropsy was performed by Lieut. W. P. Finney four and one-half hours post-mortem. The diagnosis from gross examination was: lobar pneumonia, very slight, right lower lobe; chronic fibrous pleuritis, right; moderate congestion of viscera. "No adequate anatomic lesions to account for death." The notes on the head at the necropsy were:

"The pia is thin and delicate; there is scarcely any fluid beneath it. The surface of the cortex is pinkish by numerous injected capillaries; the convolutions are not flattened. There is no exudate over the base of the brain, and only a small amount of clear cerebrospinal fluid. There is no bulging of the brain into the foramen magnum."

On examination of the formaldehyd-hardened brain at this laboratory the following notes were made:

Everywhere blood vessels, arteries and veins are considerably more prominent than normal, though not greatly so. The pia-arachnoid is nowhere certainly abnormal, although the cerebral markings underlying some of the sulci of the convexities are more obscure than normal. Similarly, over the base the nerve roots cannot be traced to their cerebral connections with the clearness that is usual. Films made from the cortical subarachnoid space show a few red corpuscles and a few mononuclear cells, some containing granules. The convolutions all seem a little flattened. On section, the ventricles are of customary size, the ependyma and choroid plexuses probably normal, though the latter are slightly redder than usual. Throughout, the cut surfaces show unusually prominent vessels; but no frank hemorrhage is seen and no other abnormality noted. Pieces were fixed in liquor formaldehydi and Zenker formaldehyd solution (formol).

Microscopic Examination.—Blocks were cut and embedded in paraffin, sectioned at 10 microns and stained with hematoxylin and eosin, toluidin blue, methylene blue and eosin, Mallory's connective tissue stain and neuroglia stains.

Sections from the cerebral cortex (temporal, occipital and parietal lobes) showed in each instance slight involvement of the meninges. The arachnoid appeared more prominent than usual because of an increased number of young cells and fibers which appeared to be concerned with the abnormally dense arachnoid trabecular network present in this case. In the meshes of these trabeculae were seen scattered red corpuscles and numerous mononuclear cells, mostly large and frequently with pigment granules or blood inclusions. No polymorphonuclear leukocytes and no organisms were seen. The cortical gray and subcortical white matter appeared normal except for engorgement of vessels (Fig. 1).

A single block from the internal portion of the brain showed the following: The corpus callosum contained small hemorrhages, the larger just visible to the naked eye, evidently several days old, but without signs of reaction about it, and in the lenticular nuclei several vessels of small caliber showed in their perivascular spaces a few red corpuscles and mononuclear cells. This picture in much more conspicuous form in sections of the brain-stem will be described later.

The third and lateral ventricles, together with the choroid plexus of each, appeared normal, as did the fornix and internal capsule.

Six sections of the brain-stem were studied at three levels of the medulla, two of the pons, and one of the mid-brain. All sections showed an intense perivascular infiltration of many of the vessels, both large and small. The vessels lying just under the fourth ventricle most constantly showed this picture in the highest degree, and here too an occasional small

hemorrhage was visible (Fig. 2). Perivascular infiltration was, however, not confined to vessels of the dorsal portion or to the gray matter, but was frequently intense in the region of the fiber tracts. Occasionally a vessel was cut in such a way as to communicate with the meninges, and the perivascular exudate might be seen extending out apparently into the subarachnoid space. Several vessels in the meninges cut transversely also showed collars of cells closely surrounding them; there was, however, no evidence of a generalized meningitis except of a very mild degree, as already described as occurring over the cortex (Fig. 3). That this perivascular infiltration was not confined to the central nervous system was also evident from such a vessel appearing in the root of the twelfth nerve. The cells making up this perivascular ring consisted chiefly of small mononuclear cells, some of which were unquestionably lymphocytes and plasma cells, and some larger mononuclear cells containing pigment granules; one cell was here seen in mitosis; also there was usually a number of red corpuscles, at times fibrin and

Fig. 4 (Case 6).—Midbrain, $\times 640$; diffuse mononuclear exudate with neurophagia in gray matter near Sylvian aqueduct.

frank hemorrhage. In many of the smaller vessels there was evidence of proliferation of the intimal cells of moderate degree; the walls of larger vessels appeared normal with the methods employed.

A second type of lesion was a diffuse invasion of the nervous tissue by mononuclear cells, including lymphocytes and plasma cells, and in some places by mononuclear plasma cells. This was especially true of the gray matter, and was also seen in the white. Neither polymorphonuclear leukocytes nor organisms were seen. This diffuse invasion was always noted in greatest degree about engorged vessels, and about those showing considerable perivascular infiltration. The nerve cells in areas of infiltration rarely lost their normal more frequently showed chromatolytic changes, and in the denser areas of cellular infiltration were there large numbers of cells and neurophagia (Fig. 4). Many cells of the exudate and young glia cells were present in these areas, and in some mitosis was visible; no young glial fibrils, however, were seen. While the exudate appeared predominantly in the

matter, there was no evidence of selection for the type of the cranial nerves. These, however, were seen to be normal, notably the motor nuclei and especially those of the fourth and the fifth cerebral nerves.

The cerebellum showed few examples of perivascular exudation and none of diffuse infiltration. The Purkinje cells with the methods used showed much variation in staining properties, and many appeared to be absent. This condition was also noted by Marinesco.

The spinal cord was not removed at necropsy.

Microscopic examination of the heart, small intestine, and lung failed to show vascular or exudative lesions as described in the brain, and in other respects appeared essentially normal.

CASE 7 (Camp Lee, A-245).—Death occurred fifteen days from the onset of symptoms. Necropsy was performed by Lieut. C. H. Iden one hour postmortem.

The diagnosis from gross examination was old adhesive pleuritis. The primary cause of death was not determined.

A note on the brain at necropsy read: "Over the left parietal lobe there is moderate injection of the blood vessels. Spinal cord shows no abnormality."

The formaldehyd-hardened brain in gross showed: "Only abnormality made out is intense congestion of all vessels, arteries and veins. No opacity of leptomeninges anywhere. Brain does not seem swollen. On palpation, however, while brain is soft and feels as if ventricles were dilated. On section, however, this sense of fluctuation is found to be due to the softness of structure, the ventricles being normal in every way."

Blocks were cut and placed in Zenker-formaldehyd solution, embedded in paraffin, and cut and stained as in the previous case.

Microscopic Examination.—Two total sections through the medulla and three through the pons were studied. Perivascular exudate, similar in type to the foregoing case, was seen throughout the brain-stem from the lowest level (pyramidal decussation) to the highest (the nucleus of the fourth nerve). The picture was less marked than in the first case both in the amount of exudate and in the number of vessels involved. The same distribution was shown, vessels in the gray matter about the canal, under the fourth ventricle, and around the apneustic being most affected, although vessels in the fillet and anterior motor columns also are involved. The asymmetrical appearance of these vessels is striking. Diffuse cellular infiltration was neither extensive nor intense in this case, and was frequently closely confined to the non-nerve vessels with perivascular exudate. Perivascular exudate in certain areas in the medulla at the level of the eighth and ninth ventricles, some of the nerve cells in the eighth descending column. Some, others, however, are not associated with exudate, even in areas about the eighth ventricle.

In the thalamus and internal capsule very few vessels are involved, although in the thalamus adventitial exudate is seen in certain areas in this territory.

The cerebellum and pons are unremarkable. An occasional small mononuclear cell is seen in the cerebellum, but no evidence of diffuse infiltration.

The spinal cord was not removed at necropsy. The gross examination of the spinal cord showed no abnormality.

perivascular exudate, but no obvious abnormality of nerve cells.

The meninges presented a picture similar to Case 1, a small amount of free blood and numerous large mononuclear cells being present. No organisms anywhere were seen.

CASE 8 (Camp Lee, 246).—Death occurred twenty-nine days from the onset of symptoms. Necropsy was performed five hours postmortem by Lieut. C. H. Iden.

Diagnoses from gross examinations were: myocardial insufficiency, dilatation of heart (right); right lung, hypostatic pneumonia base, lobar; left lung, passive congestion; passive congestion of liver.

A note on the brain at necropsy read: "Blood vessels of the pia are markedly injected. The surface of the pia is of a more pinkish tint than normal."

The brain and spinal cord were immediately sent to the Army Medical School, where cultures and inoculations were made as described below.

At this time (twenty-eight hours after the necropsy), great engorgement of the cerebral and spinal vessels was the only abnormality noted. On section, the ventricles appeared of normal size and contained a small amount of clear fluid.

The cut surface of the brain and cord everywhere showed dilated vessels but no hemorrhage nor other abnormality. Tissues were fixed in Zenker-formaldehyd solution.

Microscopic Examination.—Five sections from different parts of the cortex showed no abnormality other than a little free blood in the subarachnoid space.

Numerous sections from the cervical and thoracic spinal cord showed excessive vascular congestion, but only rarely a little perivascular exudate, and no diffuse infiltration and no certain nerve cell changes.

The brain-stem was studied in six sections, extending from a point just below the pyramidal decussation to the level of the third nerve nucleus. The same types of lesion were apparent in this case as in the two preceding, but were less marked and less extensive. In the medulla and lower pons the slightest possible perivascular exudate

was seen in a few of the vessels, and no abnormality of parenchyma was evident. At the upper pons level, more vessels showed a moderate amount of exudate and there was an accompanying diffuse infiltration of the subependymal gray. Nerve cells, however, showed little change. More marked was the very considerable exudate which is seen in the white matter just external to the red nucleus, in the neighborhood of the substantia nigra. Here were seen large numbers of mononuclear cells (some phagocytic), lymphocytes and plasma cells (Figs. 5, 6 and 7).

Section of the basal ganglia and internal capsule showed cells with perivascular exudate in both. In the thalamus there were limited areas of diffuse parenchymatous exudate or mononuclear cells and cellular gliosis.

In the anterior lobe of the pituitary, two vessels showing perivascular infiltration were seen.

Throughout the brain there was the same slight mononuclear cell infiltration as described above.

CASE 9 (Camp Custer, A-240).—Death in this instance occurred thirty-nine days after the first symptoms had manifested themselves.

Fig. 8 (Case 8).—Medulla, capillary engorgement and perivascular exudate, also diffuse infiltration of white matter.

At necropsy, the diagnosis from gross examination was: acute cardiac dilatation, right auricle and ventricle; congestion of all viscera. Erosion of stomach (postmortem?).

A note on the brain at necropsy read: "There is a slight flattening of the convolutions. The surface vessels of the brain are more engorged than usual. No changes are to be noted in or along any of the vessels. The pia-arachnoid is smooth and everywhere normal in appearance. . . . The whole brain is very soft. On section there is marked engorgement of all vessels, little droplets of blood welling up from all the vessels cut across. . . . The ventricles are not distended and the ependyma is normal. There are no changes to be made out in any of the cranial nerves."

Microscopic.—The lesions were the same in this case as in the others. Also the distribution was similar. Throughout the brain-stem, from the pyramidal decussation to the corpora quadrigemina, and in the lenticular and caudate nuclei and thalamus, there were many vessels surrounded by dense columns of mononuclear cells, frequently with blood elements intermixed. No hemorrhage into the parenchyma was seen.

If one may judge by the intensity of the perivascular and diffuse exudate, the severity of the process in this case was greatest in the upper region of the pons. In this case, more than in any other, was seen extreme invasion of the white matter, the lemniscus being the seat of intense mononuclear cell infiltration.

Here, as in other cases, there was no predilection for the cerebral nerve nuclei, and while abnormal nerve cells were seen, no typical picture of neurophagia could be found. Sections from all levels of the cervical cord appeared normal. The cortical gray showed no abnormality, but in the subcortical white matter there was an occasional vessel with a small amount of exudate or merely a cell or two.

SUMMARY OF PATHOLOGIC FINDINGS

The pathology of these four cases of so-called "lethargic encephalitis" was presented with a varying degree of completeness. The brains all appeared alike. A great degree of engorgement of all vessels was conspicuous; moreover, the pia was noted as pinker than normal, and this is explained by the free blood present in the meninges. The brains were abnormally soft to touch. In every case the chief seats of the lesions were the brain stem and the basal ganglia. The important lesions may conveniently be divided into (1) perivascular exudation, and (2) diffuse infiltration of parenchyma. While both types of lesion vary greatly in intensity, extent and symmetry, they were seen especially in the gray matter about the canal, fourth ventricle and aqueduct, though deeper tissues

were also affected, and white matter was not spared. The cells concerned in both types of lesion were all mononuclear; a small mononuclear cell and a large mononuclear cell, frequently phagocytic, many of which appear to be neuroglia cells, together with the lymphocyte and plasma cell, were recognized. Polymorphonuclear leukocytes were conspicuous by their absence even in the case of short duration. Mitotic figures appeared in small numbers both in the perivascular and in the diffuse exudate. That the two processes were interrelated is apparent from the appearance of diffuse exudate chiefly in the immediate neighborhood of affected vessels. That the diffuse infiltrating exudate was not necessarily related to a destructive process is borne out by the normal or only slightly changed appearance of nerve cells in its midst; however, when the exudate was excessive, marked nerve cell changes, including neurophagia, resulted.

Bacteria were sought for with care and none were seen.

Lesions that may be considered subsidiary in our cases were hemorrhage and meningitis. Hemorrhages were few in number and very small, so insignificant, in fact, that they utterly failed of detection in the gross examination. However, a certain amount of free blood and fibrin, mixed with the perivascular exudate, was frequently seen. Blood vessel changes were of two types. There was almost constantly evidence of proliferation of the intima in vessels in areas of exudation, those in unaffected territory usually showing no abnormality. The second type of lesion noted was infiltration of the vessel walls (especially intradural), with mononuclear cells, chiefly lymphocytes and plasma cells. This condition was observed by itself in the meninges (Fig. 3) and associated with perivascular exudate in the substance of the brain. It is likely that more of the exudate was intramurally situated than appearance indicates; this would explain the very moderate cellular infiltration of the meninges and associated low cell-count in the spinal fluid.

The cord and organs in the cases examined appear essentially normal. It is unfortunate that no notes on the root ganglia are available.

Lesions in the cerebral cortex were in all cases so existent or negligible.

EXPERIMENTAL TECHNIQUE

Inoculation experiments were carried out with material from Case 8 at the Army Medical School.

Fig. 6 (Case 8).—Midbrain, $\times 720$; same area as Figure 5; type of diffuse infiltration with plasma cells and lymphocytes.

Washington, by Colonel Russell. Under aseptic precautions the spinal dura was opened twenty-eight hours after death, and cultures (aerobic) were taken from the subdural and subarachnoid spaces, respectively; these cultures were found to be negative. With sterile precautions, specimens from three levels of the cord were then removed, macerated with sand and saline, and filtered through cotton. Injections with the filtrate were made as follows:

Monkey 1 received 1.2 c.c. by intracerebral inoculation. Monkey 2 received 2.5 c.c. by lumbar subarachnoid injection. A rabbit and a guinea-pig each received 1 c.c. intraperitoneally. A mouse received 0.5 c.c. intraperitoneally.

None of these animals became in any way sick, the monkey remaining under observation for seven weeks.

Fig. 7. Case 8. Midbrain. $\times 1000$; same area as Figure 5; granule cells and phagocytes.

Cultures taken from the lateral and third ventricle twenty-eight hours postmortem were negative.

The failure to reproduce the disease in these two monkeys does not exclude definitely the possibility of future transmission to such animals, for in the first place the filtrate used was from the spinal cord, which did not show pathologic changes to any extent, and secondly, the patient died late in the course of the disease (twenty-ninth day).

From Patient 3, eleven days after the earliest symptoms, spinal fluid was removed and injected as follows:

Monkey by lumbar inoculation, 2 c.c.; rabbit by peritoneal cavity of the crista magna, 2 c.c.; rabbit by peritoneal cavity of the crista magna, 2 c.c.; together with a small amount of serum given to produce a sterile meningitis.

All of these animals remained unaffected.

SUMMARY

All of the nine cases presented may be logically grouped under the title "lethargic encephalitis."

The onset of symptoms was always insidious, headache, malaise, weakness and vertigo being commonly complained of. Early symptoms of probably greater significance were sore throat, diplopia and always fever. That the prodromes are likely to be confusing is certain from the diagnosis "hysteria" having been made in two cases, in one of which the patient died within five days of the onset.

It was unusual to find signs of organic nerve disease in the first week of illness, and although symptoms referable to such disease undoubtedly occurred early, they were usually of such transitory character that their significance was often not appreciated until later.

By the second week—sometimes later still—a widespread organic neurologic disorder became evident, when cerebral symptoms appeared. Drowsiness occurred in almost every case, frequently developing into coma, and at times alternating with a state of irritability or anxiety. In spite, however, of an apparently clouded mental condition, orientation and cerebration were usually unaffected, until just before death.

Long projection fiber tracts to arms and legs showed profound disturbance in seven cases, as indicated by ataxias, spasticities, the Babinski reflex, and clonus. The only symptoms and signs of a focal character were referable to the brain-stem, and these were present in all. Diplopia was complained of in seven of the nine cases, although, curiously enough, oculomotor palsy was seldom actually seen, doubtless because of its transitory nature. The second most frequent focal disorder was weakness of the facial muscles, usually one-sided, a condition seen in five cases. Pupillary disturbance, irregularity, inequality and abnormality of reaction were common, and weakness of the jaw muscles was observed three times. Profound disturbance of respiration was twice noted.

Several points on the clinical side should be emphasized; the insidiousness of the onset, the recurrent and incomplete nature of the paralyses, and implication of cerebral nerves confined to motor function. To this add spasticities and ataxias caused by interference with the projection fiber systems, and a syndrome is presented which is admirably explained by the diffuse infiltrating exudative process of this disease.

The symptomatology and pathology as shown in our cases correspond very closely with the descriptions as given from France, Vienna, and England, and with other reports from this country.

As to etiology: Wiesner and Breinl assert that they have transmitted the disease to monkeys, but the former apparently did not see the organism in the original tissue, and the cases of the latter as reported suggest more typical poliomyelitis rather than this disease. Marinesco finds two types of organisms in his slides. We have neither seen organisms, nor have we been able to grow them from the cerebrospinal fluid or from the nervous system postmortem; inoculation experiments, so far as they go, are negative, as were those of McIntosh. It is our opinion, however, that further attention should be given to inoculation work.

We wish to acknowledge here the valuable service rendered by Major Tasker Howard at Camp Lee, Major Russell Cecil and Lieut. John E. Dwyer of the Army Medical School, and Major R. G. Hussey and Lieut. Henry R. Muller of the Army Medical Museum.

THE DISPOSITION OF THE SAC
IN HERNIA

EMANUEL FRIEND, M.D.

CHICAGO

Since the earliest times, efforts have been made to cure hernia by operation, and these efforts have constantly been renewed and methods have been improved on because of the unreliability of the older methods of retention. Good results were not obtained until the beginning of the antiseptic era, and at the present day the procedures formerly adopted have only a historical interest. For centuries the radical operation was practiced only by strolling laymen, who were known as "hernia cutters" (Bruchschneider). The results were poor; and in the most frequent variety, the inguinal hernia, the ligation of the sac was always accompanied by castration. For this reason the operation fell into disrepute. The craft was considered dishonorable; and in the eighteenth century, when reputable surgeons began to operate for the relief of hernia, the hernia cutters completely disappeared.

The first to apply antiseptics to the surgery of hernia were the English. They were promptly followed by the Germans, who became extreme antiseptists, and commenced to cut freely on reducible hernia. The Americans, who were largely influenced by the German school, soon followed, while the French and Italians have been the latest to adopt kelotomy.

It is my purpose here to present the various methods of the disposition of the sac, and to submit for consideration a method which I have been unable to find in the literature, and which I have found to be very successful.

Fig. 1.—Isolation of the sac from the surrounding structures well to the internal abdominal ring.

THE BASSINI METHOD

1. The Bassini method is doubtless the most common. When the sac has been exposed at the site of the superficial ring, it is traced backward through that opening to its junction with the parietal peritoneum lining the general peritoneal cavity; then after opening it is removed flush with the parietal perito-

neum by transfixation and ligature. Then it is cut away, the stump retracting into the abdomen.

2. When the sac cannot be isolated flush with the parietal peritoneum, owing to adhesions to the wall of the sac or in sliding hernias, the sac is transfixed by ligatures as high as possible, the redundant sac is

Fig. 2.—Sac cut into six ribbons.

cut off, and the stump is brought underneath the muscles (conjoined tendon) by a staple suture.

MACEWEN'S METHOD

3. The Macewen method consists in throwing the sac of the hernia into a series of folds by the introduction of a suture along the length of its long axis and then fixing the retracted sac into the tissues near the site of the deep ring.

KOCHER'S METHOD

4. *Original Method.*—A. An incision is made through the aponeurosis of the external oblique above and external to the site of the deep ring sufficiently large to introduce a pair of forceps down the inguinal canal. The forceps catch hold of the sac and drag it bodily upward and outward through the opening in the aponeurosis, and there it is fixed in front of this layer by means of suture.

B. *Modification of Method, Invagination and Transplantation (Verlagerung).*—This method is used when the sac is complete, not incised or torn in previous manipulations. Curved dressing forceps grasp the apex of the sac; the sac is then invaginated around the forceps; the forceps now enter the external oblique ring and pass underneath the aponeurosis of the external oblique until it is opposite the internal ring. A small incision is made in the aponeurosis over the forceps and deepened until it cuts through the external layer of the sac. The invaginated sac is grasped by artery forceps, pulled out and caught, a pedicle ligated and cut away, and the stump is allowed to retract back.

C. *Modification of Method, Layered Transplantation (Verlagerung).*—This method is used when invagination method is impossible because of shortness, tension, and thinness of the sac.

has required incision. The tip of the sac is caught in curved dressing forceps and is then passed through the external inguinal ring underneath the aponeurosis of the external oblique up to a point opposite the internal ring. At this point a small incision is made in the aponeurosis, and through it the sac is pulled out (not invaginated), then pulled taut, transfixed, ligated and the distal portion cut away. The stump slips back and the small incision in the aponeurosis is sewed up.

BALL'S METHOD

5. By Ball's method the sac is twisted into a dense cord, so as to throw it into a series of folds, thereby producing a prominence internally rather than an infundibuliform depression. To prevent untwisting, a ligature is tied as high as possible, and it is also transfixed below the ligature by a suture, the ends of which are passed through the abdominal parietes.

Fig. 3. Pad of knotted sac ribbons after tying of each pair of ribbons, but not yet replaced into the internal abdominal ring.

BARKER'S METHOD

6. In Barker's method, the neck of the sac is isolated, ligatured and divided, the fundus being left in situ, while the suture used in tying the neck is employed as the first suture to close the deep part of the canal. By this means it is hoped that the neck of the sac will be displaced and, hence, more satisfactorily occluded—which I doubt very much.

AUTHOR'S METHOD

The method which I would present I term the "auto sac closure." It consists (when the sac is long enough) in the usual isolation of the sac from the cord and the surrounding structure well into the internal abdominal ring. When the sac is opened at its apex, it is freed from its contents and divided longitudinally into four, six or eight ribbons, which run nearly to the base of the sac. Then each opposite two ribbons are seized with hemostats and tied together with a single knot, each successive knot overlying the preceding one, thus forming a solid pad of the sac itself. To prevent slipping of the knots, a catgut ligature, if desired, can be placed around the entire knot and the ribbon

ends cut off. Then this pad of knotted sac ribbons is reduced into the internal ring, and one proceeds with the usual method of closure of the canal.

The advantages of this method are:

1. The solid bulwark of knotted sac which lies internal to the internal abdominal ring prevents the abdominal contents from again descending into the canal.
2. It does away with the infundibular shape of the sac, which is conducive to recurrence.
3. There is less likelihood of transfixing any of the sac contents by ligature.
4. The introduction of a foreign body like catgut into the peritoneal cavity, especially if it should not be sterile, is eliminated, though this point, to be sure, is of minor importance.

I have used this method in innumerable cases in my service at the Michael Reese Hospital, and have yet to see a recurrence of the hernia.

5 North Wabash Avenue.

EXFOLIATIVE DERMATITIS DUE TO ARSPHENAMIN

REPORT OF A FATAL CASE

JOSEPH R. LATHAM, M.D. (BELHAVEN, N. C.)
First Lieutenant, M. C. U. S. Army
CAMP JACKSON, COLUMBIA, S. C.

It has been recognized for some time that arsphenamin could, when given intravenously, cause arsenical poisoning. At the base hospital at Camp Jackson, there have occurred four cases within the past five months. The most typical of these—a fatal one—is here reported.

This fatal result followed the intravenous administration of 0.8 gm. of arsphenamin. The case, in its general features, bears the stamp of arsenical intoxication. The clinical diagnosis was confirmed by abundant laboratory data.

REPORT OF CASE

J. C., a private, aged 27, in a routine examination of his company gave a positive Wassermann reaction. He had at that time no symptom or sign of syphilis, and denied any venereal history. His physical condition was excellent. An injection of 0.4 gm. of arsphenamin was given intravenously. The reaction following this was so marked that he was kept a week in the hospital. He was then sent to duty, although there was present, at the time of his discharge from the hospital, a peculiar keratoid condition of his face and neck. From his second dose, received one week later, he experienced no apparent reaction. Ten days following the second injection, he was admitted to a medical ward at the base hospital. On admission, he had no complaint other than that the skin of the face and neck was hard and red and knobby to the touch, and was burning and tingling considerably. Even then, the process was showing a tendency to generalize. On the skin of the face and neck, in addition, there were to be found areas of superficial branny desquamation. Where the process was oldest, the skin color had faded to a dull red. In the superficial layers there was a marked amount of a dirty brown pigmentation. The eyes were the seat of a moderate conjunctivitis. The ocular media were normal. The fundus showed no sign of inflammation. The external ear showed, from the first, a distinct seborrheic eczema, which was apparently an independent process, so markedly did it differ from the other skin condition.

There was, at this time, no demonstrable evidence of polyneuritis. Reflexes were equal and well balanced, and there

were no sensory disturbances. It was only after the first week that he showed any laryngobronchial catarrh. At no time during his illness did he have abdominal pain or diarrhea. The urine content and output were within normal limits. Arsenic, while present in easily demonstrable amounts, was productive apparently of no renal irritation. The phenol-sulphophthalein output at this time was 60 per cent. for the two hour period.

Four days after admission, the patient's skin began to exfoliate. The skin of the face and arms showed this most

Fig. 1.—Exfoliative dermatitis: marked pigmentation.

markedly. As the exfoliation became generalized, there appeared a moderate fever. The pigmentation, mentioned before, became extreme; especially was this true in the axillae and on the forearms. At the same time the skin of the face—at first dry and hard—now began to fissure and to weep a viscous fluid, intensely disagreeable in its odor.

Exfoliation became steadily deeper and more extensive, reaching its maximum about thirty days following the first dose of arsphenamin. The scales, which at first had been thin and parchment-like, now began to increase in size and in thickness and to slough away, leaving a basement layer which was soft and bleeding. With the scales disappeared the pigmentation. The mouth became very sore; especially was this true of the tongue, the papillae of which were enormously enlarged, the mucosa being covered by a thick fur.

Even at this time, four weeks after the first dose of arsphenamin, the only evidences of constitutional disturbance were the continuing moderate fever, and a pronounced and peculiar leukocytosis which will later be described in detail. The mind was absolutely clear. The skin inflammation, however, caused so much tingling and discomfort that sleep was impossible except as an effect of opiates.

Prior to the beginning of the deep exfoliation, the heart remained strong and the lungs clear. As the exfoliation progressed, toxic symptoms appeared and ran hand in hand with it. Blood pressure, which had up till then remained at 130 mm. or above, now sank to below 120 mm. The pulse rate mounted steadily, as did the fever. Rales appeared in the lungs; the voice became husky, and a slight, productive cough appeared. The picture was that of the so-called laryngobronchial catarrh, which is so often found in the literature referring to chronic arsenical poisoning.

Coincident with the foregoing, the urine output steadily declined, and there was, for the first time, a trace of albumin. During the seven-day period, the phenol-sulphophthalein excretion index sank from 60 per cent. to 37 per cent. for the two-hour period. The latter reflected accurately the progressive physical and mental deterioration of the patient. During the same seven-day period the nonprotein nitrogen of the blood remained low, at the conclusion of the period

being 0.0576 gm. per hundred c.c., while before admission it had been 0.056 gm.

As the exfoliation became more and more extensive, the heliethide gradually deepened. Now, for the first time since his admission to the hospital three weeks before, there was some sensory disturbance, in that the whole left upper extremity became very insensitive to both pain and temperature. The patient suffered very little now, probably because his mental acuity was so much decreased. Fever was constant, and showed a distinct tendency to rise. Stupor deepened into coma, and despite active eliminative therapy, light convulsions began to occur, these being preceded and followed by localized muscular tremors. As a result of hot packs, the mental condition cleared somewhat, and the convulsions disappeared; the general condition, however, remained very poor.

It was only after three weeks in bed that the patient began to waste. This may be explained partly by the fact that he suffered at no time from either vomiting or diarrhea, and partly by the circumstance that up to within a day or two before his death, he partook willingly of large quantities of liquid nourishment. Toward the end, however, his mouth became so sore that feeding by means of the stomach tube had to be resorted to. When wasting did appear, it was very rapid. The body was now devoid of skin, so far as function was concerned. Bleeding fissures extended down and in places through the basement layer. The exposed deeper layers had none of the pigmentation and induration of the original process.

The blood vessels showed, early in the course of the disease, evidence of severe trophic disturbance, in that the blood would extravasate from the capillaries at the slightest trauma. In the toes, this was apparently spontaneous, but the condition was especially marked in the fingers following needle puncture for blood counts. That this condition was due to blood vessel degeneration, rather than to any fault of the blood itself, is indicated by the fact that the coagulation time remained within normal limits throughout, never going above seven minutes.

The eyes, which had, as noted before, from the first shown

Fig. 2.—Exfoliative dermatitis: more advanced stage, with increased pigmentation.

a conjunctivitis, now began to show evidence of involvement of the deeper structures. The globes became sunken and flaccid, and there was decided atrophy of the orbital fat. The media became too cloudy to admit of fundus examination. When last seen, there was no optic atrophy. Culture of cells of the conjunctival sac showed only the white staphylococcus.

On the thirty-fourth day after his first dose of arsphenamin, the patient lay in coma. The lung signs, which had those of a moderate bronchitis, now began to be those of bronchopneumonia. The heart sounds became almost indistinguishable except for the sharp snap of the second sound at the base.

patient's condition progressively deteriorated and he died on the thirty-eighth day following his first dose of arsphenamin.

The laboratory data, especially the blood picture from day to day, constitute the most interesting feature of the case.

TRACES OF ARSENIC IN URINE

The urine showed traces of arsenic as late as the thirty-fourth day. The urine remaining in the bladder after the patient's death also showed presence of arsenic. It was only toward the end that there was evidence of renal irritation. Considering the comparatively small dose of arsphenamin administered, it is rather remarkable that arsenic appeared so long and so consistently. Severi¹ found in repeated experiments that, with a single dose of toxic quantity administered by mouth, the metal was completely eliminated within five days, provided the kidneys were previously normal. Withaus² considers this to be the usual result. Almquist and Welander,³ however, found weighable quantities in the urine as late as sixty days after the stoppage of the poison. The latter condition is more apt to occur when repeated small doses have been given. Yet Wood⁴ found arsenic in the urine as late as ninety-three days after a single toxic dose. In the case under discussion, the slight renal irritation which developed toward the end cannot with justice be ascribed to arsenic, when one remembers the extreme impairment of skin function. Certainly, if it had been due to arsenic it might have been expected to exist from the first; but such was not the case.

The total arsenic equivalent of the drug given was a little over 2½ grains. As might have been expected from the smallness of the dose, it was only after large quantities of the exfoliating skin were subjected to test that arsenic was found in it.

The blood showed consistently a high polymorphonuclear leukocytosis. This persisted up to within a day before the patient's death, being closely related in degree to the height of the fever. As exfoliation progressed and skin function began correspondingly to suffer, there appeared a remarkable eosinophilia. The latter condition is found in many skin diseases, notably in pemphigus and dermatitis herpetiformis, psoriasis and eczema. In all of these, however, the percentage runs usually between 5 per cent. and 15 per cent., being seldom above. At the crest of this patient's illness, the eosin cells formed over 40 per cent. of the total leukocytes. At one time there was transient improvement in the patient's condition. It was then that the eosinophils were most numerous. As the man's resistance lowered, they disappeared from the peripheral blood. During the last three days of his life, the percentage sank to zero. The accompanying chart shows graphically the relation between the fever leukocytosis and eosinophilia.

Fig. 3. Relation between fever, leukocytosis and eosinophilia. Black line, temperature; upper broken line, leukocytes; lower broken line, percentage of eosinophils in the peripheral blood.

NECROPSY FINDINGS

There was everywhere evidence of atrophy of the subcutaneous fat. The tissues themselves were very dry.

The lungs showed an extensive passive congestion, and, at the right base, was an area of bronchopneumonia.

The heart and liver were soft and pulpy to the touch, and in many places showed extensive areas of fatty degeneration. The spleen was large, very soft and pulpy.

The kidneys were somewhat congested, but did not show either macroscopically or microscopically any definite nephritis. The suprarenals were decreased in size, and the medulla was replaced by a waxy white substance, which no longer took the chronic stain.

The mucosa of the stomach and the intestine was covered by an adherent mucus; chemically, it showed the presence of arsenic. It must be remembered that the bowel is a very important pathway for the excretion of the poison from the body.

Analysis of the liver, brain and skin, as well as of the pericardial fluid, revealed the presence of arsenic.

SUMMARY

1. A fatality followed a therapeutic dose of arsphenamin, the equivalent of less than 3 grains of metallic arsenic.

2. Diarrhea and vomiting were absent during all stages of the intoxication.

3. Nephritis was not a marked feature at any time, and appeared only at the end.

4. There was apparently a decided affinity of the poison for the skin or for the trophic nerves supplying it. From first to last all the toxic symptoms may logically be ascribed to impairment of skin function.

5. Arsenic was persistently present in the urine. This was remarkable in the absence of accompanying renal inflammation.

6. There was a high leukocytosis and eosinophilia, the latter related closely to the patient's resistance. The height of the leukocytosis followed that of the fever.

7. Arsenic was found at necropsy in every tissue in which it was sought.

Tuberculosis in Brazil.—According to the statements of Dr. O. Clark in a recent pamphlet on the need of organizing a Service of School Hygiene in Rio de Janeiro, tuberculosis causes an average of 4,000 deaths every year in the urban section of that capital, in spite of the fact that the climate is most mild, the air most pure, that there is plenty of sunshine, no congestion of population, no factories, and no subways; that there is no poverty, nor any alcohol problem; that the temperature changes but little all the year round, and that there are plenty of gardens and parks and miles of beaches. It is estimated that among all the large cities of the world, Rio de Janeiro has proportionally the largest tuberculosis mortality. Taking as a basis the usual proportion between deaths and cases, the above figures mean that there are at Rio de Janeiro all the time 40,000 cases of open tuberculous.

THE FUNCTIONS OF THE INTER-
COSTAL MUSCLES *

FURTHER OBSERVATIONS

C. F. HOOVER, M.D.,
CLEVELAND

In two former publications¹ I sought to show how observations on the respiratory movements of the costal margins give us information which enables one to gain definite conceptions about the conformation of the diaphragm. Briefly stated, the intercostal muscles and the diaphragm are antagonists. The minus barometric pressure produced in the pleural cavity during inspiration is due entirely to the excursion of the ribs and the diaphragm. The costal excursion increases the capacity of the thorax in its antero-posterior and transverse diameters, and the phrenic excursion alone increases the longitudinal diameter of the thorax. If all these muscles are activated at the same moment, it is clear that to accomplish an excursion of the ribs and diaphragm, the intercostal muscles and the diaphragm must each reciprocally overcome the minus pressure created by the other. The diaphragm must overcome the minus pressure produced by excursion of the ribs before there can be phrenic excursion, and the intercostals must overcome the minus pressure produced by excursion of the diaphragm before there can be any costal excursion. The lower six intercostal muscles and the diaphragm are also antagonists in controlling the movements of the costal borders.

Unopposed by phrenic action, the intercostal muscles will cause the entire costal margin to move away from the median line and, unopposed by the intercostals, the diaphragm will draw the entire costal margin toward the median line.

If the diaphragm is paralyzed, or its costal attachments are cut away, the outward movement of the costal margin will be greatly exaggerated. If the intercostal muscles are paralyzed, the costal margins will move toward the median line during inspiration.

The intercostal muscles and the diaphragm are antagonists in determining the direction in which the costal margins will move during inspiration, but the direction in which the costal margins may move does not in any way express the intrapleural pressure during inspiration. Nor does the direction in which the costal margins move give expression to the inspiratory excursion of the lung. In other words, there may be adequate (not normal) inspiratory enlargement of the lungs in all three dimensions whether the costal borders move in a median or a lateral direction.

Former interpretations of respiratory movements of the costal borders were based on the experiments and interpretation of Duchenne, which considered only the factor of increased intra-abdominal pressure during descent of the diaphragm as the source for lateral movement of the costal borders.

CONTROL OVER COSTAL MARGINS

I proved by clinical observations and animal experiment that the balance of control over the costal margins depended on the arch of the diaphragm.

* Read before the Section on Practice of Medicine at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

¹ Hoover, C. F.: The Functions of the Diaphragm, *Arch. Int. Med.* (U.S.), 214 (Aug. 1913); *Diagnostic Signs From the Scapula*, *ibid.* 20: 701 (Nov.) 1917.

In human beings the intercostal muscles have a small margin of superiority over the diaphragm in determining the direction in which the costal margins will move. The more nearly the curve of all, or any part of, the diaphragm approximates a plane, the greater the mechanical advantage will that part of the diaphragm have in control of the costal margin to which it is attached. The anteromedian portion of the diaphragm is less arched than its lateral-posterior portion; consequently less depression of the anteromedian portion is required to give that part of the diaphragm mastery over the costal margin to which it is attached than is required in the case of the lateral-posterior part of the diaphragm.

The phrenic muscle fibers which underlie the pericardial sac are assigned to the costal margins from the subcostal angle to the eighth cartilage on the costal margin. When all the chambers of the heart are enlarged, as in decompensated hearts from myocardial or mitral disease, and when the pericardial sac is enlarged, then the anteromedian or sternocostal part of the diaphragm is depressed, and, as a consequence, the examiner will see a symmetrical narrowing of the subcostal margin during inspiration; but beyond the eighth costal cartilage the costal margins are seen to move away from the median line during inspiration.

The balance of control over the costal margin is so nicely adjusted, and depends so wholly on the curvature of the diaphragm, that any asymmetry of phrenic curve to the two sides of the median line will make itself apparent in asymmetrical movement of the costal margins.

If the left ventricle is enlarged and the right ventricle and right auricle are not greatly enlarged, the left costal margin (to the eighth rib) will move less in an outward direction than the corresponding right side, and the left side may move toward the median line if there is sufficient flattening of the diaphragm. If the right ventricle and right auricle are enlarged, and the left ventricle is not enlarged, then the right costal margin, as far as the eighth rib, will be restricted in its outward movement and may, indeed, move toward the median line with inspiration. So the direction of movement of the subcostal angle and the symmetry, or asymmetry, of movement of the two sides may be employed to interpret the arch of that part of the diaphragm underlying the pericardial sac; and, inferentially, we gain valuable evidence concerning the size of the pericardial sac and also evidences of the size of the left ventricle, right ventricle and right auricle.

SYMMETRY OF MOVEMENT

The symmetry of movement of the entire costal borders gives evidence of the symmetry of the right and left vaults of the diaphragm. Any condition which will increase the arch of one side of the diaphragm, such as enlargement of the liver or subphrenic abscess, will cause the costal margins to move farther laterally, and more promptly, than the costal margin of the other side. When the right thorax, in one instance, was filled with pus which followed the rupture of a large subphrenic abscess through the diaphragm, the right costal margin moved farther away from the median line during inspiration than did the left margin where the lung was perfectly normal.

The movement of the costal borders is a reliable index of the elevation or depression of the arch of the diaphragm.

When the lung is enlarged by atrophic emphysema or by hypertonus of the bronchiolar musculature, the costal margins are drawn toward the median line during inspiration.

In cases of pneumothorax and empyema, when the under surface of the diaphragm is convexed, the costal margin moves away from the median line during inspiration. When air is released, or fluid is aspirated so that the leaf of the diaphragm is no longer convex on its under surface, the costal margin will move toward the median line when the diaphragm is activated, although under such conditions there can be no phrenic excursion.

The movement of the costal margin is determined by the activation and arch of the diaphragm and is not dependent on the excursion of the diaphragm.

The failure to differentiate between evidences of excursion and evidences of activation of the phrenic leaf, and the failure to appreciate the mechanical significance of the diaphragmatic arch have led to misinterpretation of the action of the diaphragm.

Study of the respiratory movements of the costal margins gives valuable information concerning the conformation of the entire diaphragm, and it also enables us to recognize any disturbance of balance between the intercostals and diaphragm when the existing impairment is on the part of the intercostal muscles.

In former years, when evidences of excursion were wanting, the diaphragm was supposed to be paralyzed, and no significance was attached to the direction or degree of excursion of the costal margins.

The excursion of the abdominal wall is a measure of the excursion of the diaphragm, but the excursion of the costal margins simply indicates the resultant of the two forces which are evidenced in the direction and degree of excursion of the costal margin. These two forces are derived from phrenic and intercostal muscle activation and must not be confused with evidences of excursion of the diaphragm.

PHRENIC AND INTERCOSTAL MUSCLES

The more nearly the phrenic muscle approximates a plane, the greater mechanical advantage will it have in procuring mastery of the costal border; and the more curved the plane of the diaphragm, the less evidence will there be of its activation. It matters not whether the diaphragm is convexed downward, as in empyema and pneumothorax, or convexed upward, as in hepatic enlargement or subphrenic abscess. Although the diaphragm moves upward (in some cases of pneumothorax and empyema) during inspiration, the costal margins of the affected side will move outward during inspiration. This experience, which can be seen plainly with the fluoroscope in patients who have a pneumothorax, under positive pressure, very definitely disposes of the old interpretation of inspiratory spreading of the hypochondria, which was based on Duchenne's experiments.

Movement of the ribs and the degree and direction of movement of the costal borders give valuable aid in detecting evidences of paresis of intercostal muscles. The costal excursion very faithfully mirrors the excursion of the underlying lung. This is of great importance in physical examinations, for it enables the examiner to detect regional modifications of pulmonary excursion.

By physical examination the physician should form very definite ideas of the size, density and extensibility of the lungs. Indeed (with the exception of a few adventitious signs), all of our methods of pulmonary examination are directed toward an estimate of these three attributes of the lung. Of the three attributes, namely, size, density and extensibility, the last is the most exquisitely responsive to pathologic changes. Extensibility is the first physical attribute of the lung which is modified in all diseases of the bronchi, lung tissue and the pleurae. It requires only a few moments to palpate the respiratory excursion of all the ribs and determine the character of excursion of the costal margins. When these observations are critically performed, the examiner will have formed a definite conception of the conformation of the diaphragm, and also a clear idea of the extensibility of the upper and lower lobes of the lungs.

Although paralysis of the intercostal muscles will diminish the vital capacity of the lungs in direct proportion to the extent of the lesion, all paralyzes are well tolerated excepting one combination, and that is a paralysis of the upper half of the intercostals when the remaining lower half of the intercostal muscles are active.

REPORT OF CASES

CASE 1.—A plump, healthy looking boy, aged 2 years, was brought to the hospital on account of what seemed to be paroxysms of suffocation. Stenosis of the upper air passages was suspected.

The child lay very comfortably on his back in bed and exhibited no signs of distress unless he was engaged in play, and laughed or cried. Any activity which was attended with an increase of respiration was attended with pronounced cyanosis. Dyspnea and cyanosis were so pronounced it frequently seemed that suffocation was imminent.

Cyanosis and respiratory discomfort increased in a vicious cycle as any incentive to deep breathing was employed. The more deeply and rapidly the child tried to breathe, the worse it breathed. There was no prolongation of either expiratory or inspiratory phase. It was also observed that during these violent inspiratory efforts, the upper thorax was violently retracted and the lower thorax was violently distended, with exaggerated spreading of the hypochondria and protrusion of the abdomen. There was a genuine see-saw between the upper and lower thorax. The scapulae were intact, as was evidenced by fixation of the first rib of each side and a want of descent of the manubrium during inspiration.

During an inspiratory effort the ribs on both sides, from the second to the sixth inclusive, were strongly retracted. The seventh rib (on both sides) was stationary. From the eighth rib to the twelfth (inclusive) there was an exaggerated excursion in a normal direction.

It was clearly evident in this case that there was a marked diminution in volume of the upper lung and exaggerated distension of the lower lung during a violent inspiratory effort; the lower lung was, therefore, distended in part by air which was displaced from the upper lung during inspiration, so the patient was ventilating his lower lung in large part by alveolar air from the upper lung, and during expiration, alveolar air from the lower lung was driven into the upper lung. There was a reciprocal expansion and contraction between the upper and lower lung. During strong inspiratory efforts, alveolar air was shunted back and forth between the upper and lower portions of both lungs. Tranquil breathing was attended with adequate ventilation, but forced breathing developed a vicious reciprocal contraction and expansion between the upper and lower parts of both lungs, which caused intense air hunger and cyanosis.

There were no physical signs to indicate any disease of the bronchial tract, or lung parenchyma or pleurae. A roentgenogram revealed marked signs of tuberculous disease

of the bodies of the upper six dorsal vertebrae, in other respects revealing a perfectly normal thorax.

There were no other neurologic signs obtainable which would indicate any disease of the spinal cord or the intercostal nerves. The respiratory distress and inspiratory retraction of the second to the sixth ribs (inclusive), associated with the disease of the vertebrae revealed by the roentgen ray, seemed, however, to justify a diagnosis of motor paralysis of the intercostal muscles, which normally accomplish the ventilation of the upper parts of the lungs.

The vicious cycle of rebreathing established between the upper and lower lung was due to the flexibility of the child's ribs, as well as to the motor paresis of the upper intercostal muscles. Had the same extent of motor paralysis occurred in an older person, with more resistant ribs, there would probably have been little or no respiratory distress. This is the only occasion in which I have seen paralysis of the upper intercostals when the lower intercostals were active, and is the only intercostal paralysis which will cause reciprocal rebreathing between two regions of the lungs. I have frequently seen paralysis of the lower intercostal muscles when the upper muscles were intact and, on one occasion, motor paralysis of all the intercostal muscles with scaleni and diaphragm intact; but the patients had no respiratory distress, because there was no rebreathing between different parts of the lung.

Paralysis of all intercostal muscles on one side is also well tolerated.

CASE 2.—A girl, aged about 6 years, was brought to the hospital directly after she had fallen to the ground from a ladder on which she was climbing. The resident physician palpated what he interpreted as the body of the third cervical vertebra projecting into the posterior pharyngeal wall. The projecting mass was pushed back into position. It was then discovered that the child had motor paralysis of the left upper and lower extremities, and it was also observed that the left side of the thorax did not move with respiration. A lumbar puncture revealed a large amount of free blood in the subarachnoid space. There was complete paralysis of all the intercostals of the left side of the thorax, and there was no demonstrable evidence of any activation or excursion of the left side of the diaphragm. All the pulmonary ventilation was accomplished by the intercostals and diaphragm of the right side.

The child was not cyanotic, she had no air hunger, and there was no inspiratory retraction of the left thorax. The entire left thorax was completely immobilized. There must have been some ventilation of the left lung because there would certainly have been cyanosis at least, had all the blood passing through the left pulmonary veins been unrespired. A very moderate increase in respiratory excursion of the normal right lung would have compensated for an increase of carbon dioxide contributed to the aortic blood by unrespired blood from the left lung; but superventilation of the right lung could not prevent cyanosis from appearing under such circumstances. We would have seen the same degree of cyanosis that appears in fibrinous pneumonia of the entire left lung. Were there no ventilation of the left lung under such conditions as presented in this child, then the only area for the escape of carbon dioxide and absorption of oxygen for the left lung would have been the cross section of the left bronchus.

When we consider the estimated area of the total respiratory membrane of an adult lung to be 90 square meters, it is apparent that although a bronchus to a lung may be open, it offers a negligible area for transpiration of gases. In the case of this child, with all the intercostal muscles and diaphragm of the left side paralyzed, the only manner in which anoxemia could have been prevented would have been through some respiratory excursion of the mediastinum, for there certainly was no respiratory excursion in a longitudinal or anteroposterior diameter. There must have been some respiratory movement in the third dimension. With the disturbance of equilibrium between the right and left pleural cavities which attended intercostal and pleural excursion of the right side, the mediastinal structures moved toward the right. In this manner the transverse diameter

of the left pleural cavity was enlarged during inspiration and diminished during expiration. There was therefore no rebreathing between any two portions of the lung.

To summarize, paralysis of all the intercostal muscles, of both sides, or of one side, or the lower half of both sides, or the lower half of one side, produces no respiratory distress nor cyanosis when the patient is at rest.

Paralysis of the upper half of the intercostals of both sides, however, produces severe respiratory distress when the ribs are sufficiently flexible to admit of reciprocal expansion and contraction between the upper and lower parts of the lungs so as to cause rebreathing between the upper and lower lung.

Although this manner of intercostal paralysis is the only kind which will per se produce suffocative symptoms, intercostal paralysis of a moderate extent will diminish the vital capacity of the lung.

CASE 3.—A man suffering from syringomyelia of the cervical and dorsal cord had very moderate emphysema which was not sufficient to cause flattening of the diaphragm; but the pulmonary volume was enlarged so that the lower border of the lung stood one intercostal space lower than is normally found. The striking feature about this patient was the very small margin of cardiorespiratory reserve, which was disproportionately small for the very moderate emphysema. Physical examination and the roentgen ray both failed to detect any signs of lung or heart disease which could in any way explain the small vital capacity of the lung, which was only 1,100 c.c.

Pulmonary emphysema which would reduce the vital capacity to so small an amount must be a severe emphysema, and this man did not have severe emphysema, nor was there any evidence of cardiac enlargement, or stasis in the pulmonary circulation, or other disease of the bronchi, or lung parenchyma or pleurae. The striking disparity between the moderate emphysema and great reduction in the vital capacity could be accounted for only by evidences of paralysis of the intercostal muscles from the third to the seventh rib (inclusive) of the left side. The left costal border, from the subcostal angle to the eighth rib, was drawn toward the median line during inspiration. The left costal margin below the eighth rib and the entire right costal margin moved laterally during inspiration. When the ribs of the left side were palpated successively from above downward, all could be felt to move normally excepting the fourth to the eighth ribs, which, on palpation, revealed inspiratory retraction.

There was no evidence of disease of the underlying lung, and there was not merely a want of normal excursion of these five ribs, but there was a genuine retraction of the ribs during inspiration.

The retraction of the costal border of the left side, from the angle to the eighth costal cartilage, was explained by the normal diaphragm in this region being unopposed by intercostal muscles. Further confirmation of this interpretation of the small vital capacity was found in evidences of marked paresis of the abdominal muscles of the left side. During expiration the abdominal wall was seen to be rotated on a longitudinal axis; the median line was drawn toward the right side during forced expiration, and the umbilicus moved upward and toward the right when the patient coughed.

During the act of coughing, one could palpate an equal bursting tension over the left and right sides of the abdomen; but the abdominal wall to the left of the median line was clearly seen to be protruded, while the right side was retracted. To the left of the median line the abdominal wall was passively distended; but to the right of the median line the abdominal wall was actively contracted, when the patient coughed or made a forced expiration.

An analysis of this patient's peculiar respiratory limitations and movements became quite clear when the movements of the costal margin were employed to study the

balance of power between the diaphragm and the intercostal muscles; but aside from this point of view, his respiratory movements became a hopeless tangle.

INTERCOSTAL MUSCLES AND DIAPHRAGM

In several cases of syphilis of the spinal cord it has been possible to demonstrate paralysis of several groups of intercostal muscles by observing the respiratory movements of the entire costal margin. When the diaphragm is unopposed by intercostal muscular action, the costal border will be drawn toward the median line during inspiration; but the retraction of the costal border does not prove that there is impaired muscular power of the intercostal muscles—the intercostal muscles may be normal and the costal margin be retracted because the flattening of that particular part of the diaphragm gives the phrenic muscle mastery over the costal end. When retraction of the costal margin is an evidence of paresis or paralysis of the intercostal muscle, then the involved rib will be seen to retract throughout its course, whereas, the anterior end of the rib will be retracted, and the rib in its course will be normally elevated, when flattening of the phrenic arch is responsible for retraction of the costal border.

In studying the respiratory excursion of the ribs, one must differentiate between the significance of excursion of the costal ends, namely, the costal border, and excursion of the arcs of the ribs. The direction of the excursion of the ends of the ribs (costal border) is quite independent of excursion of the diaphragm and excursion of the arcs of the ribs. The costal border (rib ends) will move either toward the median line, or laterally, according as the pull of the diaphragm or of the intercostal muscle may have the mastery of the ends of the ribs. When the intercostal muscles are paretic or paralyzed, the costal border formed by the ends of the affected ribs will be drawn toward the median line during inspiration, and the arcs of the affected ribs will also be retracted during inspiration.

When the diaphragm is flattened and the intercostal muscles are normally activated, then the costal border will be drawn toward the median line during inspiration; but the course of the rib will move in the normal "bucket handle" arc.

Careful study of the respiratory excursions of the arcs of the ribs and of the costal border gives very valuable information on the innervation of the diaphragm and the intercostal muscles. By this study we are also enabled to visualize the conformation of the leaves of the diaphragm, and by such observations we also gain valuable information about the extensibility of the lung.

CONCLUSION

Costal movements accurately mirror the movements of the underlying lung.

When the respiratory excursions of the thorax are studied in this manner, the lung and its bounding walls take on an entirely new significance.

The lung will be appreciated as a very lively organ, which has a motility quite different from the popular conception of an elastic bag which is alternately expanded and contracted on mass in obedience to changes of barometric pressure within the pleural cavity.

1903 East Seventy-Fifth Street.

ABSTRACT OF DISCUSSION

DR. HENRY SEWALL, Denver: Since Hutchinson, in 1834, showed that the lung activity could be separated into three cycles, residual, complementary and tidal air, we have learned nothing. Dr. Hoover did not speak of the relation of the blood flow through the lungs. That is a matter of supreme importance, of course. In one subject the blood goes through in two or three times the volume that it does in another subject, and every time there is a cry or a deep respiration, that blood flow is accelerated or retarded. When a person changes his position there is a tremendous gravimetric pull on that blood, and in some people that blood does not get back to the heart, and you may think that blood does not go through the lungs. Of course, that is not just right—the blood is retarded. Very often in going about in an automobile, I feel as though I were going to faint. I know that is due to the blood being retarded and I can correct it by voluntary contraction of the abdominal muscles; I pump that blood up into my brain just as you would pump the blood into a tube. There are peculiar relations which the doctor spoke of—one of one part of the lung pumping blood into another part. This is a very interesting fact. You can demonstrate certain practical conclusions by the use of this method voluntarily. Hold your breath as long as you can, say for one minute. Have your glottis closed, and when you cannot hold the breath any longer, contract your chest and expand your abdomen and you churn the air back and forth in your lungs and you can hold it for a minute and a half. Remember that if you get caught out in the surf. Just as the surgeons are waking up to the fact that there is a field of thoracic surgery, the clinicians must wake up to the fact that there are mechanics of respiration which they have always avoided because they lack mechanical training. It is just as important as the study of the signs of appendicitis.

DR. CHARLES L. MINOR, Asheville, N. C.: For a number of years I have believed that the presence of a very small focus in the upper portion of the lung will manifest itself as clearly by limitation of the base as in any other way. I have given a great deal of study to the isthmus, and there is nothing more useful than an otherwise unexplained limitation of the motion of the base. That is extremely more valuable than the fluoroscope. The fluoroscope shows the advance and the retardation of the diaphragm; it does not show advance or retardation in the complementary space. Remtree's stethometer measures the motion of the second, third or fourth rib. The diagnosis of tuberculosis depends on the little things and summation of the different points.

DR. CHARLES F. HOOVER, Cleveland: The point Dr. Sewall mentioned—holding the breath—is somewhat aside from the subject matter which I presented; but inasmuch as Dr. Sewall brought it up, I will mention that the holding of the breath is pretty difficult to explain. For instance, if anyone of us would take a deep inspiration, if we super-ventilate our lungs for probably four or five inspirations and then take a deep inspiration and then close the glottis, we cannot hold the breath for more than about a minute. Then we exhale, and we find that the concentration of the CO_2 in the exhaled air will be about 0.23. Now, however, if we ventilate our lungs with pure oxygen, we cannot hold our breath any longer because of the rise of the partial pressure of CO_2 in the aortic blood. This is not due to a want of oxygen, but to the fact that the elevation of CO_2 in the aortic blood has compelled an inspiratory impulse. Now, if we ventilate the lung several times and take a deep inspiration of pure oxygen, we will find that we can hold the breath for three minutes. Then if we explore the air, instead of the 0.23 we will have 9.23 CO_2 . So that according to all our teaching of inspiration a man must have in his aortic blood a concentration of CO_2 which balances the alveolar air, and yet you can hold your breath very comfortably provided you have an adequate amount of oxygen. If you reduce the oxygen, you cannot hold it so much. There is no explanation of the tolerance of CO_2 in the presence of oxygen, and the intolerance of CO_2 in the presence of diminished oxygen. I simply want to show that we have not by any means explained what we term shortness of breath. It is an extremely difficult thing to explain.

STUDIES ON MALARIA CONTROL

IX. EFFECTIVE AND PRACTICAL TREATMENT OF
MALARIA TO DISINFECT INFECTED PERSONS
AND TO PREVENT RELAPSE*

C. C. BASS, M.D.

NEW ORLEANS

When a physician is called on to treat a case of malaria, usually the chief object he has in view is to relieve all clinical symptoms. The disinfection of the patient and the prevention of relapse receive secondary consideration, if any. There is great variation in the treatment of clinical cases of malaria, and still greater variation in the treatment for the purpose of disinfecting the patient. Disinfection is of greater importance than it is generally considered to be, because of the fact that if not disinfected the patient is likely to have latent malaria or to relapse with more or less harmful effect, and because of the further fact that during all the time he is a potential source of infection to others.

In a study of the frequency of malaria relapse made on 3,815 persons in Sunflower County, Mississippi, during 1918, the information obtained showed that between 50.77 and 68.86 per cent. of all persons who had attacks of malaria during the year had relapses and not new infections. It is not uncommon for persons to have from one to several attacks of malaria every year, for a period of two or three years. There are plenty of instances in which the possibility of reinfection was entirely eliminated, showing that they were relapses and not new infections.

The importance of disinfecting infected persons has not received as much consideration by practitioners as it deserves. Using the data that have been obtained in a study of malaria control in the Mississippi delta during the past three years, I have been able to estimate with a fair degree of accuracy the reduction in the prevalence of malaria that would take place if all physicians disinfected all the cases they treat. It was shown that malaria would be reduced approximately 90 per cent. in ten years' time by this means alone.¹ Every case of malaria means that the patient will continue as a potential source of infection until disinfected, and every malaria patient disinfected means the destruction of one or more sources of infection.

Malaria is one of the diseases in which the clinical symptoms are relieved a long time in advance of the disappearance of the specific infectious agent. No high degree of effective immunity is conferred by an attack of the disease in the majority of instances. Whenever sufficient treatment is given to reduce the number of parasites sufficiently, the symptoms cease, but the infection continues. Small numbers of parasites may remain in favorable locations in the tissues of the body, and probably continue to reproduce. Later, when conditions become more favorable, they may, and often do, give rise to a return of clinical symptoms, or relapse.

Though blood examination demonstrates the presence of parasites in practically all cases of clinical malaria, and in many instances of persons who are infected but have no recognized clinical symptoms at the time, it fails to demonstrate their presence in many persons who have smaller numbers but are still infected. The number of parasites may be so small that no practical examination of the blood would demonstrate their presence. As long as the patient has one viable parasite in him, he remains infected. Treatment for the purpose of disinfection is not effective, therefore, until every parasite is destroyed. When this is accomplished, no relapse occurs, nor is the patient a source of infection to others. Treatment which will destroy every parasite, and which is practical at the same time, is my subject here.

The disappearance of clinical symptoms and of parasites from the peripheral circulation cannot be depended on, therefore, to show when disinfection has been accomplished. In many instances, patients carry the infection for months, sometimes as long as a year, or even longer, without showing any clinical symptoms whatever. Then something happens that reduces the effectiveness of the means by which sufficient resistance has been maintained to retard the multiplication of parasites, and clinical symptoms of malaria develop. Such things, for instance, as sudden chilling of the surface of the body, getting wet, eating large quantities of indigestible food, the shock of surgical operations, or injuries, are frequently sufficient to precipitate attacks in persons who are infected but who have been able to resist the disease sufficiently to prevent clinical symptoms.

THE DURATION OF PROPER QUININ TREATMENT

The duration of proper quinin treatment is the only reliable guide as to when disinfection has been accomplished. Since the disappearance of clinical symptoms and of parasites in the peripheral circulation, presence of which affords the basis for a diagnosis of malaria, cannot be depended on as a guide as to when disinfection has been accomplished, we must rely on methods of treatment which have been demonstrated by experience to prevent the occurrence of relapse. Quinin is the only drug known which destroys malaria parasites and is capable of disinfecting. It is, fortunately, a very perfect specific, and I believe it can confidently be said that when properly used it will disinfect any patient. My opinion is that there are no exceptions. Perhaps the amount of quinin and the duration of administration required may, in exceptional cases, be much greater than what the average patient requires; but there surely is a dose and a duration that would be effective in every instance. Failure simply means that proper doses of quinin have not been administered or that there has not been proper duration of treatment, and not that the patient cannot be disinfected by treatment with quinin.

AVOIDANCE OF INCONVENIENCE AND DISCOMFORT

Practical treatment must be convenient and must not produce great discomfort. Even after the acute symptoms of malaria have been relieved, the patient must be given quinin for a considerable length of time to make reasonably certain that he is disinfected. On account of the fact that the treatment must be so long continued, long, in fact, after the patient thinks he is

² This is one of a series of papers to be published, based largely or entirely on malaria control work conducted jointly by the International Health Board and the Mississippi State Board of Health.

³ Bass, C. C.: Studies on Malaria Control. V. The Importance of Disinfecting All Cases Treated as a Factor in Malaria Control in a Locality of Great Prevalence, South, M. J., to be published.

well, the quinin must be given in a convenient form. During the prolonged treatment the patient is usually up and about at his usual occupation, and any treatment that puts him to considerable inconvenience would be much less likely to be continued than one that did not. Quinin is a drug that is slowly absorbed and slowly eliminated, and it is not necessary, therefore, that it be given at frequent intervals. For the purpose of disinfection, one dose a day is just as effective as any larger number of doses, and it is much more convenient to take one dose daily than a larger number. Generally speaking, it is much more convenient to take it at night before retiring than at any other time of day.

If the treatment produces great discomfort it is also not as likely to be carried out as if it did not. When given hypodermically, great discomfort is produced and, in practice, few patients are ever disinfected when this method of administration is prescribed. Sometimes quinin is given by mouth in acid solution. This is one of the most nauseating doses, and any physician who has been in the habit of prescribing quinin in this form, or who contemplates doing so in the future, should take it for a while himself. He will then be better able to decide whether or not to prescribe its use in this fashion. It is much better to give it in the form of tablets, for those who can swallow tablets, and in the more or less tasteless form of quinin in aromatic syrup of yerba santa for young children. The discomfort caused by quinin injection and by taking it in acid solution by the mouth is often a cause of abandoning the treatment before the patient is disinfected.

Quinin causes considerable discomfort, such as tinnitus, urticaria and nerve irritation, in a great many persons. Susceptibility to these unpleasant effects varies greatly with different persons. Some are rendered quite uncomfortable by even small doses, while others may take considerably larger doses without discomfort. Fortunately, there is, in the great majority of instances, no great unpleasantness produced by the amount necessary for disinfection. It is very important that the necessary dose should not be greatly exceeded because of the resulting discomfort. Otherwise, the treatment is much more likely to be abandoned before the desired results have been accomplished. There is no other specific remedy for malaria and, therefore, no other treatment to choose. Those who are affected unpleasantly by it are unfortunate, but still their only specific remedy is quinin. The sooner this fact is learned and appreciated by the medical profession, as well as the laity, the better it will be for malaria sufferers.

SPECTACULAR METHODS AND UNUSUAL SALTS

Since the treatment must be kept up for a considerable length of time to disinfect, and since the success depends very much on the patient's confidence and cooperation, spectacular methods and special salts and preparations of quinin should not be used, even if they should be as effective, dose for dose, which they often are not. So far as I have been able to learn from experimental studies, and from observation of treatment of those who have malaria, in a group of more than 40,000 persons living in a heavily infected section, there is no salt of quinin any more effective in disinfecting a patient than ordinary sulphate, and there is no method of administration that is as effective

or practical for this purpose as administration by mouth.

During 1916 and 1917, those who were found to have malaria among 31,459 persons examined in Bolivar County, Mississippi, were furnished quinin in different forms and in different size doses, to be taken for variable lengths of time in different groups. A blood examination was made of these persons subsequently, to determine the results of the different methods of treatment. From the data obtained, it appears that 10 grains of quinin a day for a period of four weeks disinfects about 60 per cent., and that 10 grains a day for eight weeks disinfects about 90 per cent. There were some instances of relapse in the case of persons who took the full eight weeks treatment faithfully.

It was also found that patients take 10 grains of quinin daily better, and more systematically, than they will take larger doses, such, for instance, as 20 grains daily. They will not take the large dose so well because of the discomfort produced, including, especially, tinnitus and dizziness, which often occur in laborers and in people under the influence of quinin working out in the heat of the sun.

As a result of this experience, we have adopted 10 grains of quinin daily, to be taken, preferably, before retiring, for a period of eight weeks, as the minimum dose that can be depended on to disinfect. (Children should be given a proper proportionate dose.) Patients thought likely to be especially resistant should be given a somewhat longer course of treatment. If judgment and care are used, most of the patients who would fall in this group can be found by giving attention to the history, which usually tells of previous relapses. Patients who give a history of previous relapses should be put on longer than eight weeks treatment.

SUMMARY

Disinfection of the patient has not received the consideration that it deserves in the treatment of malaria.

The disappearance of clinical symptoms and of demonstrable parasites in the blood cannot serve as a reliable guide as to when disinfection has been accomplished. Nor can any other known method of examination determine when the infection is eliminated. The most dependable guide at our command is the duration of a treatment that experience has shown to be effective.

Quinin, in sufficient doses for a sufficient period of time, is effective in all cases. I believe that there are no exceptions to this statement. Instances in which the treatment that is successful in average cases fails to disinfect are examples, not of the failure of quinin to disinfect, but simply of the failure of quinin in that particular dose and for that particular length of time. If the treatment be continued for a sufficient length of time, it always succeeds, even in these exceptional cases.

The treatment, to be practical, and to be carried out by the patient, must not cause great discomfort or inconvenience. One dose at night is usually more convenient than a larger number of smaller doses, and it is equally effective. Less discomfort is produced also.

The treatment recommended, one to disinfect infected persons and to prevent relapse, is 10 grains of quinin sulphate at night, before retiring, for a period of eight weeks. When there is good reason

to think a given patient will be more difficult to dissect than the average one, the treatment should be continued considerably longer than eight weeks.

NOTE.—What has been said refers to the treatment of cases without acute symptoms, or after active symptoms have been relieved. Active clinical symptoms are relieved in practically all cases by three doses of 10 grains of quinin, during each day, for three or four days.

ABSTRACT OF DISCUSSION

DR. C. S. WILLIAMSON, Chicago: We do not see very much malaria in Chicago, and yet when we do see it, it presents some interesting problems. During the past five years three cases have come under my care under almost identical conditions. The patients were young men; the diseases came on after exposure to cold in February, and the diagnosis in each case was lobar pneumonia. None of these patients had been out of Chicago for many months. None of them knew that they had had malaria before; the diagnosis was confirmed by blood examination. The symptoms were such as to lead inevitably to a diagnosis of lobar pneumonia. In one case the patient was given quinin sulphate for five months in doses of about 30 grains a day, followed by an acid solution, and at the end of that time there was a relapse. The patient had not left Chicago.

Will Dr. Bass tell us whether he believes that the temperature of Chicago might reawaken an old malarial infection or whether there is some particular strain of the parasite which must be accounted for. These cases impressed themselves on my mind because it seemed to be almost impossible to have malaria in the cold winter. One patient was working on a bridge, and you would naturally think of pneumonia and not of malaria and mosquitoes.

DR. CHARLES C. BASS, New Orleans: I do not think that we know just how exposure to cold and other influences that lower the vitality of the individual will cause relapses. It is a most common experience where there is much malaria that, given a group of men many of whom are infected and who are getting along well, if it rains and many of them get wet, sudden chilling of the surface of the body is followed in three or four days by chills and fever, although the patients had not had chills and fever before; but this sudden chilling of the body seems to affect them. Another observation that most of us who have studied malaria have made is that a constant even temperature, when there is little variation between the noon to night temperature, not as many malaria relapses are noted as during the early season of the year and later in the fall when there is great variation in the extremes of temperature. It seems reasonable to suppose that this is one of the many things that may lower the general vitality of the individual and in some way interfere with the resistance by which he holds back or prevents relapse. The shock of a surgical operation may do the same thing. Perhaps, however, when we know more about the immunity processes by which individuals are able to prevent relapses and eliminate the relapses without treatment the relapses will be fewer.

Is Your Community Fit?—A nation-wide campaign for the prevention of venereal diseases has been organized. Have you consulted your health officer on the part your city should play in this important work? Is your community planning to take advantage of the recent federal enactment and appropriation for the control of venereal diseases throughout the United States? Has an ordinance been passed which will enable your health department to take up this matter in an effective manner? Proper reporting of dangerous sources of infection and their adequate treatment and control beyond the contagious stages is essential. The establishment of places where infected persons can be given expert treatment and advice will greatly aid in limiting the spread of these diseases which are so disastrous to mankind.—*Pub. Health Rep.*, April 25, 1919.

DESIRABILITY OF PREVENTING STERILIZATION IN YOUNG WOMEN

WHEN OPERATING FOR TUBERCULOUS PERITONITIS *

J. H. CARSTENS, M.D.

Professor of Abdominal and Pelvic Surgery, Detroit College of Medicine and Surgery

DETROIT

Tuberculous peritonitis generally occurs in the young, principally in women, although it may affect either sex. After considerable experience with abdominal operations, I have found that tuberculous peritonitis is usually cured by a celiotomy. The simple opening of the abdomen without anything else being done, nothing being removed and no irrigation being instituted, has sometimes resulted in a cure. At other times, complications have been found which had to be remedied. Often the operation was performed for pus tubes, which were very properly removed on account of mixed infection.

It has become a custom with some surgeons when operating for tuberculous peritonitis to remove the tubes whether there was mixed infection or not, simply in order to close an avenue for the entrance of tubercle bacilli, which were supposed to be poured out from the end of the tube into the peritoneal cavity. I have protested against this practice for many years, because the tubercles in the peritoneum are all absorbed in the course of time, and it is my belief that the tubercles on the tubes and uterini would likewise be absorbed.

It has been asserted that in operating for appendicitis, it is often found that the trouble is of tuberculous origin. In that case I always remove the appendix, and I should also remove the tubes if the nidus of the disease seems to be there. It is at times very difficult to tell where the original infection was, or where the disease in the peritoneum started. There may be big masses of tuberculous deposits, even in the omentum, some of them solid and from 2 to 3 inches in diameter, but I never remove them nor do I take any other action. They all disappear in a remarkable manner by simple opening of the abdomen. I remove the appendix in all these cases, because the appendix is a dangerous organ to leave behind. As the result of the tuberculous infection, adhesions, twisting, and kinking of the appendix often occur, which in the future are liable to cause an acute inflammation of this organ even after all tuberculous deposits have disappeared. In the case of the tubes this danger does not exist. The patients are nearly all young women, perhaps unmarried, or married only a short time, and to remove the tubes and thus deprive them of the opportunity of motherhood I consider a bad practice.

ORIGIN OF TUBERCLES IN THE PERITONEUM

As to the origin of the tubercles in the peritoneum, on the appendix and the tubes, they are brought in and are deposited there from the lymph channels. Some of them may pass from within the intestine by a process of diapedesis into the peritoneal cavity. Most of them are probably absorbed into the circulation and are deposited. These tubercles may differ from those usually affecting the lungs. They may be, as many

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventeenth Annual Session of the American Medical Association, Atlantic City, June, 1919.

think, of the bovine kind, such as are also supposed generally to affect the joints of children and to be due to drinking milk from tuberculous cows.

This tuberculous trouble of the peritoneum seldom comes from the vagina and uterus, and is not poured out of the end of the tube. In fact, such a case has never been demonstrated. I have curetted several hundred patients. I have had them all examined microscopically, and in only one case was there a tuberculous condition on the mucous membrane of the uterus, and that was in a woman, aged 55. I have also seen only one case of tuberculosis in the vagina.

SYSTEMIC ORIGIN OF TUBERCULOUS PERITONITIS

One point I want to make is that tuberculous peritonitis is of systemic origin, and does not come from the outside through the tubes; hence, there is no occasion to remove and close them.

Another point I want to bring out is that, whereas there are thousands and thousands of tubercles deposited in the peritoneum in large bunches, even on the omentum, forming hard, firm tumors from 3 to 4 inches in diameter, all these are rapidly absorbed after a simple operation without any apparent trouble. If nature takes care of all the tubercles in the peritoneum and omentum, the dozen or two that are on the uterus, or on the peritoneal covering of the fallopian tubes, will also be taken care of, and the woman will be restored to perfect health with all her generative organs in good condition.

INDICATIONS FOR THE REMOVAL OF THE TUBES

The only case in which the removal of the tubes is justifiable is when another kind of infection has also taken place in the tubes, and they have been closed either before or after the tuberculous deposit in the peritoneum has taken place. Then we are obliged to remove the pus tube completely in many cases, and there is no reason why we should not do that even though the patient has a tuberculous peritonitis. But even in these cases, we sometimes merely resect the tube or some part of it, with the view of possible pregnancy in the future, and we can do this also in some cases with the disease under consideration.

REPORT OF CASE

Mrs. P. T., aged 28, operated on by me, July, 27, 1915, for tuberculous peritonitis, made an excellent recovery, gained rapidly in flesh and blood, and menstruated normally until April 13, 1918. September 1, she felt life, and was delivered, Jan. 27, 1919, by Dr. A. K. Moon. She had a retroverted adherent uterus, and had had no children. When operating for this condition I found she also had tuberculous peritonitis.

I had one other case in which I operated, July 16, 1918, and in which the patient became pregnant in January, but aborted.

These cases show that after a conservative operation for tuberculous peritonitis, women may become pregnant; hence, no woman in the child-bearing period should be sterilized unless there are other causes than tubercles in the peritoneum.

DIFFICULTY OF THE DIAGNOSIS

The difficulty of making the diagnosis is well known. I often find symptoms and indications that there might be such trouble, and when operating find some other kind of infection in the tubes. In other cases in which I simply operate for displacements and adhesions, I suddenly run across a tuberculous peritonitis.

AUTHOR'S METHOD OF OPERATION

All physicians differ in their technic more or less, and I do not know that the differences are very important. In my earlier cases I washed out the peritoneum with a 1:10,000 mercuric chlorid solution. A quart of the solution is poured in, the opening is closed with the hand, and the body is shaken so that the fluid comes in contact with every part of the peritoneum. I think this irritates and stimulates the peritoneum—probably produces phagocytosis. I do not know whether the mercuric chlorid does any good, but I know it does no harm, as I empty the peritoneum and then put in a saline solution—gallons and gallons of it—and wash the peritoneum out thoroughly so as to be sure that there is no mercuric chlorid solution left behind to produce poisoning. I then sew up the abdomen with No. 2 plain catgut in layers, closing first the peritoneum, then the muscle, and then the fascia with a running suture. I never sew up the skin. I use sterile adhesive plaster, and the wound generally heals promptly. Formerly, I used silkworm-gut or silk sutures, but as these act as a drain, and in the tract of each suture a deposit of tubercles made its appearance, and each stitch hole showed a dark red spot as seen in healing or healed tuberculous sinuses, I stopped this method of closure. Drainage of the wound is not considered, because it first of all does not drain, and secondly, is liable to result in the development of fistulas and ulceration of the bowel.

CONCLUSION

If nature will remove the myriads of tubercles in the peritoneum in whatever part they may be, nature will also remove the few that can be found in the tubes, and the latter need not be removed on that account, and the women be thus needlessly sterilized.

1147 David Whitney Building.

ABSTRACT OF DISCUSSION

DR. J. SHELTON HORSLEY, Richmond, Va.: Not many years ago every surgeon had his own particular pet method of treating tuberculous peritonitis. One would let the sunlight in, another put in drainage tubes and still another would have his own mixture of dusting powder. The peculiar part of the matter is that nearly all the patients got well. This is not due to the particular method used but to the fact that each man was unconsciously working on the principle of producing hyperemia, which is the enemy of tuberculosis. When Dr. Carstens opens the abdomen and removes the appendix or any other organ he induces hyperemia, and this conduces to the recovery of the patient. As to the question of drainage; that is important. In ordinary peritonitis we did not drain in a mechanical way; every abscess in the peritoneal cavity was drained uphill and patients get well from appendiceal abscess drained uphill as readily as do those drained by the cul-de-sac, because the drainage tube acts as an irritant, promotes hyperemia and that assists in curing the tuberculosis. Mutilation of the patient by taking out the tubes because she has tuberculosis does not remove the pathology.

DR. J. H. CARSTENS, Detroit: All I want to plead against is this everlasting removal of tubes and the sterilization of women for every little measly thing that might be the trouble. I decidedly object to that as it is bad practice. When a person has tuberculosis of the lungs or some other organ of the body, you do not remove those organs; you treat the patient systemically. Why should you not do that in this kind of a case? The bacilli are killed and then disappear.

DIETETIC HELPS IN DIABETES

ROSE R. DONK, M.D.

BUFFALO

The treatment of diabetes demands exact regulation of diet. That proper dietetic management is amply rewarded by good clinical results has been shown by Allen.¹ That such management admits of fairly definite lines of procedure has been further shown by Joslin.²

It is with difficulty that the practitioner finds time to carry out such estimations of diet as are necessary in treating diabetes. The problem is to get the patient sugar-free and acid-free and to teach him to keep so. This is to be done primarily by the regulation of protein, fat and carbohydrate intake.

Is it possible to prearrange such combinations of food in series as shall form a convenient basis for the estimation of diabetic diets?

work. If, in becoming sugar-free and acid-free, the patient lowers a high urea index, he has scored an extra point.

The use of fat will be regulated by the patient's condition and by laboratory determinations of acetone, diacetic acid, ammonia and acidity of the urine. Alveolar air determinations are a reliable guide concerning acidosis. The Marriott apparatus is simple and sufficiently accurate.

The laboratory record of a case of severe diabetes is shown in the accompanying chart. The periods of fasting are indicated. The early record, showing acidosis and considerable sugar, contrasts with the later maintenance of a good report. When the patient went home he was able to take care of 83 gm. of protein, 147 of fat and 58 of carbohydrate—1,887 calories. The record of this case is shown through the kindness of Dr. Charles G. Stockton.

The patient, on presenting himself, had the clinical appearance of severe acidosis. His alveolar air was

Laboratory record of a case of severe diabetes.

The dietetic requirement depends on the age and weight of the patient, on his accustomed diet and his adaptability to changes, on his condition as to obesity or leanness, and on his habits of exercise. Acidosis must be prevented. The metabolic derangement in diabetes concerns protein and fat as well as carbohydrate. The benefit from fasting, or "rest" days is due to this fact. Carbohydrate tolerance is in itself relative. This is shown in those cases in which the carbohydrate tolerance improves when the protein allowance is not kept at too high a level.

Laboratory analyses are a necessary guide for feeding. Such study, besides helping to secure improvement of the patient, is full of interest and suggestion. With a low blood urea the diabetic patient commonly puts out a large amount of urea in the urine. Like the patient with hyperthyroidism or with fever, he over-excretes and overconcentrates. However much this represents disturbed general metabolism, it may well represent also increased kidney stimulation and over-

work. That is, close to the danger point. The blood sugar was 0.47 gm. in 100 c.c. of blood. The urinary ammonia was high, as were also the acetone and diacetic acid. These figures and others are shown in the chart.

Various gradations of diet are necessary between the fasting periods, and thereafter, until the patient shall have become accommodated to caloric values that will maintain him satisfactorily. The morning's laboratory findings may show necessity for a change which may need to be made in time so that orders may be given both to the cook and to the grocer.

What combinations of protein, fat and carbohydrate are likely to be needed? Tables here shown illustrate such values as are helpful in following the scheme of treatment outlined by Joslin,³ which he presents also in the form of directions to the patient.⁴

¹ Joslin: Treatment of Diabetes Mellitus, Philadelphia, Lea & Febiger, 1917.

² Joslin: Diabetic Card, Form J. S. Boston, The C. C. Group, 310, 105 State Street.

A diet virtually fat-free precedes the fasting period. Patients not having special tendency to acidosis are, according to this plan, put on from 100 to 200 gm. of 5 per cent. vegetables³ and any desired amount of thin broth (containing no fat, little salt and low protein). Patients accustomed to full feeding must start with higher values of carbohydrate. Daily halving of these amounts will precede their final removal for the days of fasting, and avoid putting the patient too quickly on his own reserves of fat.

Table 1, Column 1, shows values for the 5 per cent. group of vegetables increasing 200 gm. at a time, protein being thus increased 4 gm. and carbohydrate 6 gm. for each two hundred. The 10 per cent. vegetables may be calculated in this column, 100 gm. of these being equivalent to 200 gm. of the 5 per cent. group. Any desired amount of 15 per cent. vegetable multiplied by 4 is approximately expressed as 5 per cent. vegetable. When feeding values are low, the 5 per cent. vegetables help satisfy appetite by their bulk. If values are higher, some of the 10 per cent. or of the 15 per cent. group are selected.

Table 1, Column 2, adds 30 gm. of potato to Column 1; Column 3, 30 gm. more, and Column 4, 30 gm. more. Columns 5, 6 and 7 represent the addition of bread, 30 gm. at a time. Throughout the tables here given, each column represents the amount of the preceding column plus the amount of a given food indicated at the head of the column.

represents 50 gm. of protein and 102 gm. of carbohydrate.³

The diet here given contains the equivalent of 2,200 gm. of 5 per cent. vegetable, 90 gm. of potato and 30 gm. of bread. It contains 102 gm. of carbohy-

Table 1 serves in the days immediately preceding or following a fast, when fat is to be given in negligible amounts.

ILLUSTRATION OF THE METHOD

The patient has been limiting carbohydrate of his own accord, is a moderate eater, and has no particular tendency to acidosis.

He may be given 100 gm. of carbohydrate (provided this is not more than he has been having and not too sudden a decrease). Fats should be omitted. Protein, from 50 to 100 gm., may be given.

Table 1, Column 5, at 102 gm. of carbohydrate calls for 2,200 gm. of 5 per cent. vegetable or equivalent, 90 gm. of potato, and 30 gm. of bread. This

tolerance and fat tolerance are low, it is rarely possible to gain much by too great an increase of protein. Consequently, in Column 5 another egg (6 gm. of protein and 6 of fat) is added. If greater increase of protein is desired before the admission of fat, the whites of eggs may be given (the white of one egg contains 3 gm. of protein). In the next two columns, the use of cream and butter leads to a slow increase of the fat, though this is still kept below the protein. Addition of lean meat, 30 gm. at a time, makes possible a gradual protein increase, and 20 gm. of cheese (American pale)⁴ increases both protein and fat moderately and contains only a decimal part of carbohydrate. Since the protein is ordinarily not to be increased to exceed

3. For lists of the 5, 10 and 15 per cent. vegetables see publications cited in other Note 1 or Note 2.

4. Atwater and Bryant: The Chemical Composition of American Food Materials, Bull. No. 28, U. S. Dept. of Agric., Washington, D. C., 1906.

the normal of 100 gm., addition of fat is now made slowly but more continuously, the protein in the table having reached from 74 to 102 gm.

It is to be noted that eventually, if the diabetic is to get good caloric value, he must do so by habituating himself to the use of fats, even allowing that he has good tolerance for carbohydrate; and, if one supposes, for example, such tolerance to be at 100 gm. the patient can have 100 gm. of protein and 100 gm. of carbohydrate, 800 calories. If he is to have even as high as 2,000 calories a day, 1,200 of this amount must then be given as fat, i. e., 133 gm. of fat.

When carbohydrate is being reduced the patient may be so relieved by diminished thirst that he takes pride in drinking very little. This tendency should

VITILIGO AND SYPHILIS

it a different signification, a fact to which I have previously called attention.¹ A recently observed designation of white scars, which are produced by gummas or by tubercular syphilids as vitiligo, is an extreme example of what appears to me to be a misuse of the term.

* Read before the Section on Dermatology at the Second Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

1. Lane, J. E.: Albinism, Lentiginism, Vitiligo, *Med. Rec.* 90: 98, 1916.

In this paper I use vitiligo as defined by the French school of dermatologists, not with the intention of making an etiologic distinction between some of the different dyschromias, but because the French definition is clear, definite and limited; because it is the one definition that is accepted by an entire school of dermatologists, and because I see no escape from confusion except by limiting the subject under discussion. The obscurity of the etiology of many of the dyschromias necessitates, for the present at least, the clear differentiation of the distinct clinical types, although it is possible and even probable that many of them have the same causation, and vary clinically with the degree of activity of the etiologic factor, as it is also possible and likely that some identical manifestations may have different etiologies.

DIFFERENTIATING SYMPTOMS

Since Hardy and Bazin, the French have differentiated vitiligo and leukoderma, which had previously been used synonymously, and which to a large extent are still so used by German, English and American dermatologists. Referring to the German usage, Besnier and Doyon,² in their translation of Kaposi, said that "for us there is no achromatic vitiligo; vitiligo is always both achromatic and hyperchromatic."

Vitiligo, then, is defined as an acquired dyschromia, characterized by the development of one or more sharply limited spots of depigmentation surrounded by a more or less extensive hyperpigmented border, showing no modification of the structure or function of the skin.

It is sharply differentiated from leukoderma, which is an acquired achromia only (that is, achromia without any attendant hyperchromia), and it does not include the rare leukomelanoderma of Fournier nor the areolar pigmentary syphilid of the neck, described by Hardy in 1853, and later so thoroughly studied by Fournier and others.

FORMER VIEWS OF ITS ETIOLOGY

Those who have studied vitiligo have suggested many diseases as its cause, in fact almost all of the diseases with which it is occasionally associated have been considered. As is usual in diseases of obscure etiology, disturbances, defects or diseases of the nervous system have frequently been invoked to cover a lack of information, and such different nervous conditions as tabes and sudden fright are suggested. One case is even reported in which a fright during the night was, the next morning, found to have produced a patch of vitiligo (I suspect the author meant leukoderma) covered with hair which had bleached at the same time.³ Among other diseases which have been mentioned as possible causes of vitiligo are hyperthyroidism and hypothyroidism, exophthalmic goiter and myxedema, Addison's disease, chorea, psoriasis, pernicious anemia, colitis, various diseases of the biliary organs, scarlet fever, various diseases of the eye, traumatism and autointoxication, lichen planus and giant colon. And McDonagh⁴ has recently suggested disturbances of the sympathetic nerve system.

RECENT VIEW OF ITS ETIOLOGY

The possibility of vitiligo being of syphilitic origin is a comparatively recent suggestion, though in 1882 Leloir⁵ had noticed its frequent occurrence in tabetics. This, however, was before tabes had been accepted as a syphilitic disease. In 1889 Tenneson⁶ called attention to the occurrence of vitiligo in syphilitics, and a few years later others noted the same thing. Little or no attention was paid to these observations and it was not until 1902 that syphilis seriously entered into consideration as a possible cause of vitiligo. In that year Marie and Guillaum⁷ Souques⁸ and Marie and Crouzon⁹ reported cases and aroused considerable interest in the subject by definitely propounding the question of whether there was an etiologic relationship between them.

In 1905 Thibierge¹⁰ published an article reviewing the previous observations on the question and at the same time reported three cases of vitiligo in patients in whom vitiligo had been present for some time before the acquisition of syphilis. He recognized the possibility of the acquired syphilis being a second infection of a patient with attenuated hereditary syphilis, but deemed it improbable, as demonstrated cases of such infections were extremely rare. Thibierge did not entirely reject the theory of the syphilitic origin of vitiligo but remarked, as previous observers had, that the question was difficult and that a large number of observations would have to be collected before a conclusion could be reached.

Thibierge's observations apparently discouraged interest in the subject for some time, as it attracted almost no attention from that time until four or five years ago. The discovery of the Wassermann reaction had in the meantime added a means of demonstrating syphilis in many cases in which it had previously not been demonstrable. In 1914 Crouzon and Foix¹¹ and others called attention to the presence of vitiligo in hereditary syphilides.

The following recent statements are fairly typical of the various opinions that are now held in regard to the syphilitic etiology of vitiligo:

Darier¹² says, "I have been struck with the relative frequency of syphilis in patients having vitiligo, as have several other authors; we cannot, however, at present admit that a syphilitic origin exists, and still less can we admit that all vitiligo is dependent on this infection." Pautrier¹³ says, "The syphilitic origin of vitiligo is manifesting itself more and more frequently since it has been searched for systematically especially by means of the Wassermann reaction." Hudelo¹⁴ says, "In spite of everything, the opinion which tends to attach certain cases of vitiligo to syphilis is becoming

ing general." Milian¹⁵ says, "Vitiligo is a pure syphilitic manifestation."

REPORTS OF CASES IN WHICH ITS RELATION TO SYPHILIS IS DISCUSSED

In this paper I have attempted to collect the case reports in which the question of the relationship of syphilis and vitiligo is discussed, and have examined most of the literature on the achromias and dyschromias published since 1906, that date being a convenient starting point, as it was the year of the publication of the discovery of the Wassermann reaction. It has, however, been impossible to consult much of the German literature of the last few years.

It is impossible in a paper of this sort to relate the details of the individual cases reported. It suffices to say that I have included only such cases as conformed to the definition of vitiligo given above and only those cases in which the question of the presence or absence of syphilis was mentioned. As might be inferred from previous remarks, it was surprising to find how many conditions are described under the name of vitiligo, and hence the large number of cases so reported that could not be included in this summary.

It should be noted that a considerable number of the cases were in patients suffering with quaternary syphilis of the central nervous system, although I have not indicated them. Table 1 gives the results obtained.

In a total of 118 cases of vitiligo sixty-one, or 51.7 per cent., were demonstrated to be syphilitic; nineteen, or 16.1 per cent., were hereditary syphilis; fifteen, or 12.7 per cent., had suspicious though not characteristic signs of hereditary syphilis; forty-two, or 35.6 per cent., were negative, or if the suspicious but unproved cases are included, fifty-seven, or 48.3 per cent., were negative.

There are, however, certain evident characteristics of statistics of this sort which prevent them from being taken at their face value. The chief one is that they are composed for large part of reports of one or two cases by different observers, many of whom have reported positive cases only, perhaps having been interested in the subject for a short time and having chanced on a case or two in which syphilis was evident. Such statistics are bound to give an unwarrantedly high percentage of positive cases. The statistics are likely to be of more value when a considerable number of cases have been carefully studied by one observer. Among the reports given above, those of Joltrain, Vignolo-Lutati, Withe and his associates are of especial interest.

Joltrain examined eighteen patients with vitiligo, of whom thirteen, or 72.2 per cent., were syphilitic; three, or 16.6 per cent., hereditary, and five, or 27.8 per cent., were negative. The details of the examinations made by Joltrain are not given, but they were undoubtedly thorough, though examination of the spinal fluid was probably not made in the negative cases.

Vignolo-Lutati examined fifteen patients, of whom five, or 33.3 per cent., were syphilitic; three, or 20 per cent., hereditary, and ten, or 66.7 per cent., were negative. The reports of positive cases showed careful investigation of the patients and though nothing is said in regard to those found not syphilitic, it is to be presumed that these were examined with the same care. Here again it is probable that the spinal fluid was not examined in the cases that were otherwise negative.

15. Milian: *Discussion de Pantrier et Rabreau*, *Bull. Soc. franç. de dermat. et syph.* 25:319, 1914.

The report of Withe and his associates is of the greatest value and deserves closer examination. The patients on whom the report was based were studied at the weekly meetings of a group of English, French and Belgian army officers during the war. All but

two of the patients were soldiers, two were women. The opportunities for study of the patients were ideal, as all desired examinations could be made. The patients were all carefully examined, spinal fluid examinations and provocative injections of salvarsan were made in doubtful cases, revealing three positive cases that would otherwise have remained negative or unproved.

Fifty patients were examined, of whom fourteen, or 28 per cent., were syphilitic; five, or 10 per cent., were hereditary; fifteen, or 30 per cent., showed signs suspicious but not conclusive of hereditary syphilis; twenty-one, or 42 per cent., were negative; or counting the suspicious but unproven cases as negative, thirty-six, or 72 per cent., were negative.

The results obtained by these three observers show a striking similarity. Taken together, they give the results shown in Table 2, all unproved cases being classed as negative.

TABLE 2.—RELATION OF VITILIGO TO SYPHILIS IN THE CASES OF THREE OBSERVERS

	Number of Patients	Syphilitic		Hereditary		Negative	
		No.	Per Cent.	No.	Per Cent.	No.	Per Cent.
Joltrain.....	18	13	72.2	3	16.6	2	11.1
Vignier-Lafitte.....	15	5	33.3	3	20.0	7	46.7
Witke et al.....	50	14	28.0	5	10.0	31	62.0
Total.....	83	32	38.5	11	13.2	34	41.5

Of eighty-three cases of vitiligo, thirty-two, or 38.5 per cent., were in syphilitics. Not included in the figures given in Table 2 there were in Witke's series four additional patients who had vitiligo previous to contracting syphilis. These observations confirm those made previously by Thibierge, though their deduction differs from his. They conclude that "this fact is not an objection to a primary hereditary infection. Binary syphilis must be especially frequent in the attenuated forms of hereditary syphilis."

Remarking on the fifteen patients who showed signs suspicious of hereditary syphilis, but in whom syphilis could not be certainly demonstrated, Witke and his associates say that "if vitiligo begins in infancy, it frequently coexists with signs which may be interpreted as belonging to a benign form of hereditary syphilis; on the other hand, the classical signs of hereditary syphilis are lacking in such cases." The deduction made by them from their results is that "it is impossible to arrive at the definite conclusion that there is a relation of cause and effect between syphilis and vitiligo, but the intensive study of the cases (including reactivation) is causing this hypothesis to gain ground."

It seems to me that this is a conservative conclusion to be drawn from their cases, as well as from the other cases here collected, and that it is as far as present evidence permits us to go.

Up to the present no other disease has been demonstrated to be present in anything like this proportion in patients with vitiligo, and one deduction at least is certain, that the search for syphilis is demanded in every case of vitiligo.

I will close with the subject with which I began by making the suggestion that while the etiology of the dyschromias remains as obscure as it is at present, it will assist a little in clarifying the discussions on them, to differentiate the different clinical forms as sharply as possible. The use of the term vitiligo as defined by the French school seems to be the logical one.

ABSTRACT OF DISCUSSION

DR. WILLIAM ALLEN PUSEY, Chicago: With reference to the distinction between leukoderma and vitiligo, which the French make, there is no ground for such a distinction. Leukoderma means a loss of pigment in an area with an increase of pigment around it. I have never seen a case

without this increase of pigment around it and when it did not appear macroscopically it could always be found microscopically. I submit that the opinions on vitiligo and syphilis are not conclusive and until they are proved conclusively why should we suppose that anybody with a white spot on his skin has syphilis? Why should anybody who sees a dyschromia on a person's skin think of syphilis? It quite often causes it but in quite a different form, just as syphilis causes an alopecia, but a true alopecia is quite different from syphilitic alopecia. We have a number of other granulomas, why not indite them? Leukodermias are not rare; vitiligos of the type Dr. Lane describes are not rare, and in my experience they have not occurred in people in whom I could find syphilis or where I had good grounds for suspecting syphilis. I have not made a Wassermann test for vitiligo and I have not made spinal punctures for vitiligo because I feel that a person who is still alive is entitled to some consideration, but I have watched for syphilis in cases of vitiligo and I am willing to say that in my experience I have found nothing to strengthen that ground.

DR. HARRY G. IRVINE, Minneapolis: It would be extremely unfortunate to regard with suspicion any one who has a white spot on the face. I have watched very carefully, with negative results. We examined fifty patients carefully for syphilis. After examining twenty-five or thirty the results were so much in the negative side, only two or three cases having been found in which syphilis was present, that we gave up the work.

DR. FRED WISE, New York: I agree with Dr. Pusey that I cannot differentiate the French vitiligo and our leukoderma. I also agree with Dr. Pusey in regard to the relationship between vitiligo and syphilis. However, vitiligo may be produced in people due to changes which syphilis may also produce. Vitiligo may be produced by headaches or cholelucitis or any other reason in the same way that syphilis produces it, by the endocrine glands.

DR. JAY FRANK SCHAMBERG, Philadelphia: I have seen vitiligo begin simultaneously in a young woman who developed an exophthalmic goiter. There are numerous reports in the literature referring to disturbances in the thyroid gland and concomitant to vitiligo. Syphilis is such a widespread disease that we must expect to find a certain percentage of vitiligo in syphilis. Dr. Lane's paper is valuable because it enables us to study the two affections. I believe with Dr. Wise that the lodgment of spirochetes in certain places may result in vitiligo. We all recall that in recent years there was a tendency on the part of some authors to associate scleroderma and syphilis. There is no doubt that vitiligo may be found in a large number of syphilitics, but I cannot believe that syphilis is the cause of vitiligo.

DR. JOSEPH ZEISLER, Chicago: I have had a lady under my observation for several years who has had vitiligo which did not change very much. About six months ago she developed a scleroderma and recently a zoster on the chest. It is well known that all these conditions are attributed by many observers to disturbance of the trophic nerves. So far as vitiligo and syphilis are concerned, I have noticed a few cases of coincident syphilis and vitiligo and also diffused symptoms of syphilis, but not of causal relationship, simply a coincidence.

DR. HENRY H. HAZEN, Washington, D. C.: It seems to me that the matter of pigment around the edges of these patches is due to the amount of exposure to the sun. I know of one instance in which seven members of the family have vitiligo, but when they are in the house in the winter or when they are ill there is practically no pigmentation. In the summer time when they are exposed to the sun the border is more pronounced. I cannot see that there is much difference between the cases with hyperpigmentation and those without; I think it is a question of sunlight. I have examined twenty-one patients who consented to a blood Wassermann test, and only one had a positive Wassermann reaction.

DR. HENRY R. VARNEY, Detroit: We are familiar with the conception of the French, but I must agree with Dr. Pusey that I cannot differentiate these two conditions. I believe

that much is due to the color and race of people who are examined.

Dr. JOHN E. LANE, New Haven, Conn.: I do not think Dr. Pusey thought I had an argument of the syphilitic origin of vitiligo. I did not intend to give that impression, but the frequency with which syphilis occurs in the general population accounts for much of it. We get reports which are not accurate because they are reported by different observers, who get only 33 per cent. of syphilis. That is considerably more than the French give, but we certainly could not put it down as of etiologic significance. Dr. Schamberg refers to exophthalmic goiter. I found a large number of such cases recorded in the literature and that a cause looks likely in a certain number of cases. As far as the pigmentation being due to the sun is concerned, I do not believe that is entirely so. It may be in some cases, but some of the most deeply pigmented patches occurred on the body where it was covered with corsets and other clothing, where the action of sunlight could have very little, if any, effect. My point in separating vitiligo from the other dyschromias was not for differentiation. My point in calling attention to that was to impress on us that we cannot give a different definition for vitiligo every time we write on the subject. I think it is perfectly satisfactory to use the terms vitiligo and leukoderma synonymously. If everybody would define them as Schamberg does in his book, a white spot with a hyperpigmented border, that would be absolutely satisfactory; but when you look through the textbooks on the subject you are merely confused. McDonough says it is usually surrounded by a hyperpigmented border; but at the end of the paragraph he says this certainly is the exception and not the rule. Some authors say the change may be primary or secondary. You cannot include the syphilitic of the neck in vitiligo; we know the etiology of that, and it simply is to differentiate the pure achromias which we are studying that I brought that point out.

THE PSYCHIC FACTOR AS AN ELEMENT IN TEMPERATURE DISTURBANCE

SHOWN BY SOME OBSERVATIONS IN THE
SELECTIVE DRAFT*

FRANK B. WYNN, M.D.

INDIANAPOLIS

Medical men are quite familiar with the temperature variations associated with the commoner clinical syndromes. Pneumonia, typhoid and similar conditions often present such typical febrile reactions that physicians are prone to associate the merely clinical picture with the temperature curve, little considering the underlying pathologic physiology of the variation. But fever and temperature elevation are hardly synonymous. In the words of MacCallum¹: "Although elevation of body temperature is one of the salient points, it is by no means the only characteristic, nor is it itself always to be regarded as an infallible sign of fever."

Clearly, it is of considerable practical importance to recognize and interpret the type of temperature change which is unaccompanied by noticeable clinical signs. This kind of variation has been noted repeatedly, particularly by physiologists, who have definitely shown, both in the case of man and of certain experimental animals, that exercise,² the taking of food³ and changing of posture⁴ are accompanied by very distinct

temperature variations. In the literature are numerous instances of diurnal temperature fluctuation in man and lower members of the animal kingdom. The daily amplitude of the curve is 3 degrees F.⁵ The thrush, seagull, pigeon and owl have a fairly constant curve, the amplitude varying inversely with the size of the bird.⁶ Monkeys have a definite diurnal curve, rising and falling with activity and rest, with an amplitude of 4.5 degrees F. Man's diurnal wave resembles the monkey's, except that the limits of variation are narrower, and the contour of the curve seems less affected by changes in activity.⁶

The credit for observing and attempting to interpret some of these obscure temperature changes belongs, principally, to the physiologists. In large measure, they are also responsible for studying and ascertaining, at least in part, the physiologic determinants of body heat control. It will be well to review briefly some of these forces and the influences modifying them; for it is only through familiarity with these facts that temperature variations, particularly of the nonfebrile type, become explicable.

HEAT REGULATION

That body temperature depends on a balance between heat production and heat dissipation is generally accepted, but the mechanism maintaining the balance is a mooted question. The evidence of earlier workers seemed to establish the existence of a "heat center" at the base of the brain.⁷ Richter⁸ noted that a dog with a normal temperature of 101.5 F. shivered on lowering, and perspired on rising, the temperature from this point; the same dog, with a fever of 104.7 F., showed the same reaction when his temperature was varied from this new level. Another investigator⁹ observed no temperature variation following antipyretics or septic injections after section of the basal cerebral nuclei. With the "heat center" theory came the convenient and attractive "thermostat" concept¹⁰ of febrile reactions; that the center is set for one level in health and another in disease, the latter, of course, representing the optimum for the body's defensive mechanisms. According to Hewlett,¹¹ in disease "the nervous centers which normally control the body temperature appear to be so deranged or, one may say, so stimulated, that they regulate the body temperature at a new and abnormally high level."

But despite this evidence, many more recent workers¹² are less certain of a special heat center. Pembrey,¹³ after several weeks of careful post-natal observation of heat control in young mammals and birds, concludes that the compensation between heat production and loss brought about by physical and chemical means is enough in itself to regulate temperature. Moore,² noting no temperature change in animals after needling the caudate nucleus and then extirpating it and the cerebrum, believes there is no cerebral heat center. In cautiously reviewing the question, Soliman¹⁴ concludes that while it is attractively convenient to assume a special heat regulating mechanism

(probably throughout the midbrain, especially in the region of the corpora quadrigemina) there is no binding evidence of such a center.

Whatever the regulating medium—be it physiologic balance or specific nervous mechanism—the physical processes it controls, the actual determinants of the balance, are heat production and heat dissipation. Heat dissipation, since largely dependent on such

Because of these difficulties, most investigation in this direction has been on man. The temperatures of the human brain itself,¹⁹ and of the body,²⁰ during mental activity, have been noted with somewhat varying results. Though Clifford Allbutt,²¹ in a lengthy series, found no changes in body temperature after mental work, other observers have noted rises of 0.2 to 1.3 degrees F.²² The data of this paper have reference, not so much to mental activity, as to fear and suspense in their relation to temperature variation. Membership on a draft examining board has enabled me to observe a fair number of selective service candidates at the time of their physical examinations (Series 1 in the accompanying tabulation.) It has also been possible to take temperature of 130 applicants taking a nurses' registration examination (Series 2). In forty of this series (Group A), the temperature was taken immediately before and after the examination; in the other ninety (Group B), during the first and last hours of the examination. The data may be thus summarized:

Series 1. The average temperature of 324 subjects, over two thirds of whom showed temperature elevation, was 99.3 F. Of the remainder, about one half were normal; the rest, subnormal.

Series 2, Group A. The average temperatures of forty subjects immediately before and after state board examination were 98.9 F. and 98.3 F., respectively.

More than two thirds showed 0.6 F. elevation before the examination. Three fifths showed over half a degree depression after it. About three fourths showed an average fall of 0.9 F. between readings.

Group B. The average temperatures of ninety subjects during the first and last hours of state board examination were 98.7 F. and 98.6 F., respectively. Only one half showed a fall between readings, averaging scarcely half a degree.

processes as sweating and vasodilatation, is manifestly under sympathetic control.¹ Heat production has been variously attributed to changes in muscle tone¹⁵ and to variations in metabolism.¹⁶ Many physiologists—among them Pembrey and Starling—believe that the muscles, which "comprise by weight over one half of the soft parts, are the main element in heat production, heat formation varying with the state of their tone." Though Hirsch and Rolly,¹⁷ after studying curarized animals, deny this function of the muscles and believe carbohydrate combustion in the liver responsible, the work has not been confirmed. In fact, curarized animals have since been observed to be poikilothermic.¹⁸ If this conception of temperature-determining forces is kept clearly in mind, the explanation of nonfebrile variations in body heat becomes less difficult.

PSYCHIC INFLUENCES

Physiologists some time ago made a start in associating definite physical causes with the characteristic fluctuations of the diurnal curve. Of more practical clinical significance would seem to be the relation of such psychic states as suspense and anxiety to temperature. Obviously, animal experimentation is impracticable in this connection. The frightened rabbit, tied to the operating board, shows temperature elevation,⁴ but whether from fear, struggle or both is manifestly uncertain.

Chart 1.—Temperatures of 324 drafted soldiers at time of physical examination. Each intersection of curve with vertical line records readings on five subjects.

Chart 2.—Temperatures of 130 nurses before, during and after state board examination: solid line, first reading; broken line, second reading. Each intersection of curve with vertical line represents readings on five subjects; thus, x, x is amplitude for one nurse, and y, y for another.

The draft figures clearly indicate a tendency to temperature elevation which is too uniform to be attributable to diurnal variation alone. Unfortunately, the exact time of the readings was not recorded, but the examinations extended through the day, and the tendency to elevation apparently characterized morning

as well as afternoon. At the time of the observations the men were stripped and were in a well-heated and ventilated room, quietly waiting their turn for physical examination. (Only 5 per cent. of them gave evidence of acute infection or active tuberculosis.) Bodily surface exposure, as perhaps the only obvious physical basis for the temperature disturbance, should be borne in mind; but its importance is questionable, since its absence in Series 2 did not modify the tendency of the readings. The men naturally presented a fairly uniform mental complex—suspense, mental concern, and unrest.

The rôle of nervous tension in elevating temperature is equally interesting in Series 2. The average

some way retarded heat dissipation, set the "heat center" at a higher level, or through more direct nervous pathways increased muscle tone or bodily metabolism. The important clinical fact is the obvious result—temperature elevation from apparently psychic, rather than physical, influences.

APPARENT FEVERS

The clinical application of the data is plain. If psychic states can so elevate temperature, it is obvious that such an elevation, plus a diurnal rise, might well simulate a genuine febrile reaction. Fortunately, such an apparent fever would be less likely to mislead the clinician now than formerly. Thanks to the growing tendency of internists to assume the physiologic point of view, it is now not the individual symptom alone, but the entire clinical complex, that governs in making a diagnosis. Nevertheless, in a certain group of cases (for example, incipient pulmonary tuberculosis), paucity of physical signs may render most important the accurate interpretation of the single question of temperature variation. Before sending to the mountains that borderline pulmonary case with the "afternoon fever," the physician must first ascertain that there is fever, and that the rise is not merely the aggregate result of the mental state and a normal afternoon increase in metabolism. This is accomplished only by enlisting the individual patient's confidence and carefully and repeatedly determining the temperature at times and under circumstances which, in the particular case, minimize the psychic element.

SUMMARY

1. Physicians are prone so to forget the physiology of heat control that they associate with various temperature curves definite clinical entities, despite the fact that temperature elevation does not necessarily mean fever.

2. Though early work suggested the existence of a special heat center, present evidence is that a complex of bodily factors controls the balance between heat production and heat dissipation, the latter depending largely on cutaneous vasomotor and secretory changes; the former, on variations in muscle tone.

3. Two series of individuals observed by the author, under circumstances associated with considerable nervous tension, showed distinct elevation of temperature in a large percentage of cases, the degree of elevation varying directly with the gravity of the situation facing the individuals.

4. The fact that psychic states can so influence temperature should make the clinician cautious in interpreting apparent febrile reactions when clinical signs are meager. In such cases, a psychic rise plus diurnal elevation may lead to false conclusions, unless the actual physiology of temperature variation and the influencing factors are kept clearly in mind.

ABSTRACT OF DISCUSSION

Dr. F. M. POTTINGER, MONROVIA, CALIF.: This question of temperature is an interesting one to me. If we could get away from the idea that there is an absolute normal, it would help. Of course, there is a near normal, but not an absolute normal. The point in temperature is the difference between heat production and dissipation; 85 per cent. is dissipated through the skin. The vasomotor nerves are under sympathetic control. When a patient comes to me for examina-

EFFECT OF SUSPENSE AND ANXIETY ON TEMPERATURE*

Series 1:

Average temperature: 324 men at draft examination, 99.3 F.

* The author is well aware of the inaccuracy of the oral thermometer. For more refined physiologic work its unreliability has been demonstrated (Donnelly; Brit. M. J., 1445 [Feb. 27, 1909]). However, the fact remains that it will continue to be the average physician's guide. And though more desirable, it was quite obviously impracticable in these series to observe rectal temperatures or that of the freshly voided urine. Instead, three minute oral readings were taken, with accurately standardized thermometers, which were carefully shaken down between readings. Spare area was taken to place each instrument properly and to see that the lips were kept tightly shut around it.

† Group A consisted of forty nurses. First reading taken before passing out state board questions; second, after completion of the examination.

‡ Group B consisted of ninety nurses. First reading taken during first hour of the examination, that is, after the passing out of the questions and the resultant break of the suspense of anticipation. Second taken during the last hour of the examination.

temperatures for each of the groups showed a most suggestive relation to the time they were taken. For example, before receiving the examination questions, the average elevation was 0.3 degree F.; during the first hour of the examination, it was 0.1 degree F.; during the last hour there was no elevation, and after the examination there was 0.3 degree F. depression. It is reasonable to suppose that with the beginning of the actual work—the expending of pent-up nervous energy, and in question answering—the tension was relieved and the heat regulating mechanism began to reapproach its normal. Furthermore, the relaxation after examination may conceivably have resulted in a general hypotonia sufficient to produce subnormal deviation. It is, after all, primarily a physiologic question whether in both series the psychic state of tension in

tion, I always allow from half a degree to 2 degrees according to the condition of the patient. One cannot deduct anything from the temperature at the time of the first examination because the patient is nervous, anxious and worried and a little elevation of temperature means nothing. There is no doubt that there is a nervous temperature because certain types of nervousness act through the sympathetic nervous system and cause disturbance of the vasomotor system which dissipates the heat. It does not seem to be well known that a temperature elevation preceding menstruation is apt to be greater than following the menstruation. In many women we see a temperature of 99 F. for the days before menstruation and a drop immediately after. I think we have done harm in depending on temperature elevation for a diagnosis in tuberculosis work. Dr. Wynn's work is interesting and suggestive. The men in the tin mines of Cornwall work in four hour shifts because they work at a temperature of 102 to 104 F. Any one who plays tennis in the hot sun will find that his temperature goes up to 102 F. but it is physiologic and dilatation of the peripheral vessels soon follows. If an individual has not control of the peripheral vessels, his temperature will not fall soon.

DR. EMANUEL LERMAN, New York: The question that Dr. Wynn has brought up is one of great importance because there are quite a number of causes of febrile action without a focus of infection. Rise of temperature can be produced by disturbance of the ductless glands, by cerebral causes or by disturbances of the sympathetic nervous system; from pressure on the liver; in embolism without bacteria; injecting salt solution into the blood stream, which causes a hemolysis and rise in temperature; plugging of the ureter by an aseptic stone. I have had two such instances where the culture behind the stone was absolutely sterile. Dr. Pottenger referred to menstrual temperature. I have seen not only gradual rise of temperature before the menstrual period but a chill. One patient was operated on for appendicitis and no appendicitis was found. Thyroid disease may elevate the temperature. It is not generally known that women may have elevation of temperature off and on for years caused by ductless gland disturbance. In the whole group of erythemas described by Osler there is temperature elevation. In cases of cerebrospinal meningitis, after the meningitis has run its course and only scar tissue remains at the base, the patient has a high temperature without any infection being present. After lumbar puncture the temperature may rise, without infection. I know one case in which such an elevation persisted for one week. There is no doubt that in Dr. Wynn's cases there was excitement. It is necessary to exclude tuberculosis and to exclude infections in the sinuses.

DR. H. S. PLUMMER, Rochester, Minn.: Temperature regulation is an equilibrium between heat production and heat elimination. It is a question of heat elimination and not of heat production. If you do not disturb heat elimination, heat production can go up enormously. We see temperature elevation in hyperthyroidism, but this fact shows how well the body is able to take care of heat production when the elimination is perfect.

DR. FENTON B. TURCK, New York: This is a physiologic question which is subject to experimental methods, and does not require clinical guessing. I introduced thermometers into the stomach and into the bowel; I placed them on the skin. Then interrupting the circulation in the leg caused autolysis and by massaging the leg a drop in the temperature took place. When autolyzed tissue reaches the circulation the reaction against it causes the rise in temperature. Many diseases are produced by autolysis of the tissues. By means of antidiolies you can immediately increase the temperature and restore it to normal by these biologic methods.

DR. GEORGE D. HEAD, Minneapolis: It seems to me that in a number of these subjects we have been reasoning in a circle. All the observations with regard to temperature on so-called normal men have not been controlled as carefully as they ought to have been. Our experience in the war clearly proved that many of our young men after repeated examinations by local boards and by our best specialists were inducted into service harboring a concealed form of

some infection, a tuberculous infection, in the large percentage of cases. At Camp Devens we were astonished at the large number of men returning to this country from France with active tuberculosis. No matter how well a man may look or how well he may feel, if you are going to make any scientific observations with relation to temperature elevation, you must first determine whether they are tuberculous. There is one of the defects in our observations with relation to temperature elevations in so-called normal persons. How do you know that they are normal? I protest against calling these men neurotics or circulatory asthenics or effort syndrome until we know whether they are normal.

DR. EDWARD F. WELLS, Chicago: I was a member of one of the advisory boards of Chicago. One of our boards sent a number of draftees to us with temperatures from 99.5 to 102 F. Many of these young men showed no evidences of local infection but they had a temperature elevation which could scarcely have been of psychic origin because in each instance we saw them three times. The inference was that there was some local infection.

DR. FRANK B. WYNN, Indianapolis: I agree with Dr. Turck that the factor back of it all is biochemical in nature, but the contention of my paper is whether the etiologic factor causing this change was one of suspense and anxiety in entering the service. There was a nervous and muscular hypertonus, the equivalent of muscular exercise, increasing metabolism in the body, and as a result I think there was a biologic change. Primarily, however, it was a psychic factor.

Clinical Notes, Suggestions, and New Instruments

REPORT OF A CASE OF PYLORIC ULCER PERFORATED DURING FIRST WEEK AFTER GASTRO-ENTEROSTOMY

EARL I. CARR, M.D., LANSING, MICH.

I desire to report a disastrous occurrence which unexpectedly took place in a case which seemed to be one of a common class, in which cure is expected and in which it would seem that a fatality could occur only because of error or lapse in technic. However commonly this occurs, I think it is not frequently recognized, and I feel that attention should be called to this possible accident.

HISTORY OF CASE

April 12, 1919, W. J. W., aged 40, machinist, came to me complaining of stomach trouble which had existed intermittently for fifteen or sixteen years. His family history was negative. He stated that he had never been seriously ill except for scarlet fever in childhood, and had never had any physical trouble except that for which he came. The present trouble, which had been an annoyance for many years and had caused him to choose his diet carefully at times, had not presented a serious aspect until within a few months, during which time his loss in weight had amounted to about 10 pounds. A dull, nagging pain in the epigastrium had interfered with thought and work and had caused him to decide to have a thorough investigation and to be willing to submit to any necessary treatment. The distress he experienced a short time after eating he described in classical fashion, but he did not give a history of having vomited or of having passed black stools. He had been greatly constipated of late.

Examination revealed a slender man weighing 125 pounds, 69 inches tall, with small panniculus and normal color, and with an anxious expression. The nose, throat and chest were negative. There was a sore spot which the patient could pick out with one finger in the epigastrium near the center. The abdomen was scaphoid and the musculature tense. Fluoroscopic examination six hours after the last barium meal showed a 25 per cent. stomach residue; a dilated duodenum, which seemed to contain the sore spot; ileac stasis; free colon, and the appendix not tender and not filled. The Wassermann was negative and the urine normal.

TREATMENT

He was operated on, April 17. An indurated ulcer about the size of a large hickory nut, with a crater which would just admit the tip of the index finger, was found in the anterior side of the pylorus. There was firm scar tissue about the base but no adhesions to the base; there was no suggestion, even, of impending perforation. The appendix was fibroid. A low posterior gastrojejunostomy and appendectomy were done under nitrous oxid anesthesia. The patient was returned to bed in good condition, and the usual post-operative treatment was followed. Proctoclysis was instituted, and the liquid was retained. For slight nausea and sense of fullness the patient was given a lavage on several occasions, and the washings showed bile but no blood. His progress was considered fairly normal until the sixth day, when the patient's expression changed and he became restless. He vomited on that day, and a lavage was done, the washings, which were completely recovered, containing bile. On the seventh day the circulation was impaired, and later in the day the patient died. A necropsy revealed the gastrojejunostomy wound to be completely healed. The induration about the ulcer had subsided to one half its former size, and the base was perforated, the diameter of the perforation being equal to that of an ordinary lead pencil. There was suppurative peritonitis.

Just when this perforation occurred I do not know. Thinking over the case, I can recall no time that can be decided on as the time of perforation. This condition of the patient on the sixth day suggested peritonitis, and on the seventh day that diagnosis seemed certain, but from an undetermined cause. That the patient's condition was critical became apparent only a few hours before his death, and not until investigation was regarded as out of the question.

EXAMINATION FOR PLASMODIA

J. W. TORPETY, M.D., MARLIN, TEXAS

I have noticed for years that patients with latent malaria often, after a hot bath, are taken with a chill and fever. For more than a year it has been our custom to have all patients suspected of having malaria take a hot blanket pack with hot fomentations over the spleen and liver one-half hour before the blood is taken for examination. Plasmodia can be found in many such cases otherwise negative.

Open Safety Pin Passes Through Baby.—Dr. W. F. Doonittle, Cleveland, writes: March 30, Harriet B., a nursing infant, put into her mouth an ordinary tin-tipped safety pin 1½ inches long. The mother tried to reach it by inserting her finger, but the child gulped the open pin down backward without seeming to be distressed. Roentgenographic examination disclosed the pin lodged in the stomach and open at an angle of 20 degrees. The pointed portion was downward and directed toward the pylorus. As no disturbing symptoms were apparent, and especially on account of the delicate age of the infant (8½ months), it was decided not to risk an operation, but to follow, at least temporarily, an expectant plan of treatment. The nursing babe was started on well-cooked oatmeal, mashed potato, bits of softened bread, etc., in addition to the breast feedings, with the idea of their bulking about the pin and assisting its passage. A little powdered slippery-elm was daily mixed with the food as a mild emollient, selected as least likely to cause too vigorous peristaltic action of the bowel. The parents were directed to screen each stool carefully and report promptly anything unusual in the child's condition. The patient continued to show no signs of distress, but thrived on the mixed diet so that a marked facial eczema due to exudative diathesis became quite cleared up. Another roentgenographic examination, May 1, revealed the pin as still in the stomach, but with its back now toward the pylorus. There were no disturbing symptoms, and the mode of treatment was continued. Just two weeks later the pin passed the anus uneventfully.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

CHLOROSANE (See New and Nonofficial Remedies, 1919, p. 137).

Chlorosane (McNeil).—A brand of chlorosane containing from 35 to 40 per cent. of chlorine in stable (nonactive) combination.

Manufactured by Robert McNeil, Philadelphia, Pa. No U. S. patent or trademark.

When assayed by the Carius method chlorosane (McNeil) contains from 35 to 40 per cent. of chlorine.

DICHLORAMINE-T (See New and Nonofficial Remedies, 1919, p. 138).

Dichloramine-T (McNeil).—A brand of dichloramine-T complying with the N. N. R. standards.

Manufactured by Robert McNeil, Philadelphia, Pa. No U. S. patent or trademark.

Pituitary Solution-Abbott.—Liquor Hypophysis, U. S. P.—A sterilized solution of the water soluble extract of the posterior portion of the pituitary glands of cattle. It is free from chemical preservatives. It is standardized according to the method of Roth (Bulletin 100, Hygienic Laboratory, U. S. P. H. S.).

Actions and Uses.—See New and Nonofficial Remedies, 1919, p. 204.

Dosage.—From 0.5 to 1 Cc. to be injected intramuscularly or subcutaneously. May be increased or diminished according to indications.

Manufactured by the Abbott Laboratories, Chicago. No U. S. patent or trademark.

Ampules Pituitary Solution-Abbott, 0.5 Cc.—Each ampule contains pituitary solution-Abbott 0.5 Cc.

Ampules Pituitary Solution-Abbott, 1 Cc.—Each ampule contains pituitary solution-Abbott 1 Cc.

Posterior lobes of the pituitary body of cattle are finely minced, extracted with slightly acidulated water, the solution boiled for ten minutes and filtered. The resulting extract is sterilized and then adjusted so as to correspond with the Pharmacopoeia standard.

Pituitary solution-Abbott is a transparent liquid, colorless and having a faint characteristic odor.

Pituitary Extract-Lederle.—A sterile solution containing the active principle of the posterior lobe of the pituitary body. It is physiologically standardized according to the method of Roth (Bulletin 100, Hygienic Laboratory, U. S. P. H. S.).

Actions and Uses.—See New and Nonofficial Remedies, 1919, p. 204.

Dosage.—Usually 0.5 to 2 Cc. intramuscularly, cautiously increased if necessary.

Manufactured by the Lederle Antitoxin Laboratories, New York. No U. S. patent or trademark.

Ampules Pituitary Extract-Lederle, 0.5 Cc.—Each ampule contains pituitary extract-Lederle, 0.5 Cc.

Ampules Pituitary Extract-Lederle, 1 Cc.—Each ampule contains pituitary extract-Lederle, 1 Cc.

Posterior lobes of the pituitary body of cattle are extracted with water slightly acidulated with hydrochloric acid, and containing a little camphor. The extract is standardized and filtered into ampules.

Pituitary extract-Lederle is a clear, almost colorless solution having a faint characteristic odor. It is standardized so that 1 Cc. of the solution diluted 20,000 times is equal in activity to a 1:20,000,000 dilution of betaninazyl-ethylamine hydrochloride when the isolated uterus of the virgin guinea pig is used.

ANTIDYSENTERIC SERUM (See N. N. R., 1919, p. 209, and THE JOURNAL, April 19, 1919, p. 1136).

Lederle Antitoxin Laboratories, New York.

Antidysenteric Serum (Polyvalent).—Marketed also in syringes containing 50 Cc. each with sterile needle.

STREPTOCOCCUS VACCINE (See N. N. R., 1919, p. 291, and THE JOURNAL, April 19, 1919, p. 1136).

Lederle Antitoxin Laboratories, New York.

Streptococcus Vaccine (P. I. Lactis).—Marketed also in 10 Cc. and 20 Cc. vials; in packages of four 1-Cc. vials containing, respectively, 50, 100, 200 and 400 million killed streptococci; and in packages of four syringes containing, respectively, 50, 100, 200 and 400 million killed streptococci.

SATURDAY, JULY 5, 1919

BREAD AND BRAN

The question of the physiologically preferable mode of milling wheat cannot be regarded as a new problem raised by the war. It is an old issue which was brought anew into prominence by the shortage of bread grains throughout the countries whose food supplies were directly menaced by the great conflict. Every bread-eating nation clings to bread as long as possible. The immense significance of this fact is emphasized by the official estimate of the part which wheat plays in the dietary of the American people. Thus it is stated¹ that, excluding the widely consumed breakfast foods, macaroni, spaghetti and similar products, and referring only to the three common flours, patent, entire and graham, they supply one fifth of the protein and one quarter of the carbohydrate of the average dietary. The government specialists remind us that in times of stress even greater reliance is placed on bread, and it is a matter of repeated observation that those of relatively small incomes tend to make bread a predominating portion of the diet. If we are short of bread grains, says Taylor,² we must modify our bread. In case of a very great shortage, other cereals must be substituted for bread.

In the most common modern milling processes the germ, together with a large portion of the outer layers of the wheat kernel, is removed. The removal of the germ which contains practically all of the wheat fat or oil lowers the energy value somewhat but improves the keeping quality of the flour. Our standard wheat flour represents less than 75 per cent. of the original weight of the cereal grains from which it was prepared. The remainder appears in the trade as grain offal or mill-feed, and is chiefly used as a protein concentrate in the feeding of live stock, especially dairy cattle. In this way the fraction of the wheat not directly eaten by man is nevertheless converted indirectly through the medium of animal feeding into food fit for human consumption.

There is a widespread belief that the highly milled flour, which has lost some of the protein and the vita-

mins of the original wheat kernel contained in the outer layers of the latter, is less nutritious on that account. Against this may be arrayed the argument that bread made from wheat flour including the whole of the wheat germ (graham flour) or a part of it (entire wheat flour) and the outer layers of the kernel has a lowered digestibility, particularly in the case of the protein. Obviously any gain in energy-producing elements or in protein in a richer initial product may be more than offset by the failure of the human alimentary apparatus to utilize it. From a careful review of the experimental literature on this subject a government expert in the U. S. Department of Agriculture has reached the following conclusion:

The results of numerous studies conducted both in this country and abroad to determine the digestibility of wheat flours containing little, if any, bran as compared with the digestibility of flours containing all the bran normally present in the grain show that the protein and carbohydrate of flours from which the bran has been largely removed is more completely utilized by the human body than the protein and carbohydrate of flours prepared from the whole grain.³

Since vitamins are available in abundance in many types of foods other than the cereal grains, the removal of this category of food factors from wheat through milling need not become a matter of serious concern unless the dietary becomes exceedingly restricted in respect to the sources of its nutrients. It is, of course, readily conceivable that an enforced ration of highly milled cereals, meat, vegetable fats and sugars may lead to malnutrition. For example, Chick and Hume⁴ have reported that among groups of people living on restricted diets in which bread made from patent flour formed a large proportion of the total ration, beriberi was very common; whereas people living on similar diets, but with bread made from the entire kernel replacing that made from patent flour, were rarely affected. The food habits of most persons living amid a liberal variety of dietary opportunities are such that under ordinary circumstances deficiency disease as a result of the use of highly milled cereal is scarcely to be feared.

What shall be said of the bran factor in the relative digestibility of different grades of flour? The widespread use of wheat bran as a laxative is based on the assumption of the comparative indigestibility of this portion of the grain despite its admitted richness in protein. Strangely enough there are few, if any, accurate data from human subjects regarding the actual degree of utilization of wheat bran apart from its inclusion in flour. Hence we welcome the new report on this subject⁵ from the Office of Home Economics in the U. S. Department of Agriculture. The results of tests with fine bran indicate that the protein supplied by the bran was 45 per cent. and the bran car-

bohydrate was 57 per cent. digested, while the results of the tests with coarse bran indicate a digestibility of 28 per cent. for the bran protein and 56 per cent. for the bran carbohydrate. This tallies with the statement of Pannwitz,⁵ who found that the protein of fine rye bran was 44 per cent. digested. Although the extreme comminution of the bran which supposedly renders the hard particles more pervious to the alimentary digestive juices improves its digestibility somewhat, even in this most advantageous physical form the outer layers of the wheat kernel are at best poorly utilized. The quantities of bran eaten were large; and Holmes,³ who conducted the experiments, reports, as might be expected, that the amount of feces voided by the subjects during the tests was larger than normal. This condition was noted by all the subjects regardless as to whether they were of active, athletic or sedentary habits. Some of the subjects found the bran diets decidedly laxative. Little, if any, difference was noted by the subjects as a whole between the laxative effects of the fine and of the coarse brans.

Another feature associated with the presence of an abundance of bran in the diet is clearly brought out by the government digestion experiments. The "coefficients of digestibility" of the other nutrients—the fats and carbohydrates of the diet—are somewhat diminished by the presence of the bran in the ration. In explanation of this altered utilization of the entire diet it is suggested that the bran may stimulate peristaltic action to such an extent that the food materials are not as completely absorbed as is normally the case when they pass through the alimentary tract without increased peristalsis. In any event, we now know more definitely than hitherto what becomes of bran in the diet and how it influences the fate of the constituents of the ration during their alimentary sojourn in the body.

PHYSICAL EXERCISE AND PHYSIOLOGIC FITNESS

Enthusiasm for an end or object that is unquestionably good sometimes defeats its own purpose by encouraging extremes of performance which damage rather than improve. This has doubtless often been true of athletics. Pursued ostensibly to promote personal welfare, physical exercise is not infrequently carried to a point of overdoing which results in ultimate injury rather than benefit.

At the present time the value of exercise in the development of good physique is being menaced, we fear, by the extreme claims of propagandists whose chief aim is to exploit the physical unfitness of the average American business man for their own personal advantage. Widely advertised systems of exercise, gymnasiums for the "busy man," physical training "institutes," and work-to-be-fit wonders have become

part of an organized commercial effort to "save" the lethargic American gentleman.

Possibly many of these schemes represent a wholesome beneficial influence. A serious difficulty lies in the lack of suitable criteria as to the benefits derived; or rather in the failure to recognize where the limitations of muscular effort lie for the untrained. Perhaps some index will be found in the recent studies on aviators. In an address before the Harvey Society, Henderson¹ pointed to the increasing frequency among aviators of a condition of "air-staleness." This is described as the effect of repeated slight oxygen deficiency of a person who does not become acclimatized. It is a condition, Henderson says, closely similar to, perhaps identical with, "overtaining" or staleness, the physical and nervous impairment of athletes.

The Manual of the Medical Research Laboratory of the War Department's Air Service states that the ability to endure comfortably and well high altitudes is dependent on the ease and quickness with which the adaptive responses in the breathing, the blood and the circulation take place. An explanation of the difference in reaction observed among the members of a group of men when at a high altitude is to be found in the degree of individual, physical fitness. In persons damaged by disease, overwork, unhygienic living, or weakened by inactivity and by loss of sleep, the power of adjustment is as a rule below par. The normal equilibrium of the body is so nicely adjusted that under usual conditions the physiologic balance is largely maintained by adjustments that are made with little or no expenditure of energy. There is a certain range of greater or less breadth through which the external factors of the environment may be varied and yet be met by an automatic adjustment of the physiologic processes in the body which will preserve the vital balance of the mechanism. But beyond a certain point, specific for each organism, changes in the external conditions will necessitate more radical alterations which will tax the compensating mechanisms to the utmost capacity in order to prevent disaster. Theoretically the organism which has been called on repeatedly to make a certain kind of adjustment will be the one most capable of responding when an extraordinary demand is made.

Translating these observations from the new physiology of aviation to the physiology of training for fitness in everyday life, we are probably justified in concluding that the test of exercise as a beneficent performance lies in the physiologic adjustments that it induces. If the heart reduces its rate of beating and is less sensitive to moderate exertion, the training is commendable. Training should make the heart and other muscles work better and endure fatiguing exercises better than the untrained heart does. Conse-

quently, if the heart reacts excessively as a result of work; if there is a rapid rise in pulse rate which returns only after a long interval to its normal, the fundamental aim of exercise for health has not been accomplished. The symptoms of an overtaxed mechanism are at hand. However advantageous vigorous training may be in the great majority of cases, failure to adjust to the increased demands of work is always a signal to desist and an indication that other modes of perfecting the organism should be sought.

TISSUE POISONS IN THE GENESIS OF SHOCK

A biologist recently remarked that our laboratories resemble "up-to-date shops for quantity production of fabricated hypotheses"—that they are full of fashions and go from one extreme to another. A reviewer of the literature on shock might well have the same conviction. Shock, like many other pathologic phenomena, is the result of an interplay of numerous agencies which may be initiated in different ways. One observer centers his attention on some particular factor in the community of causes while he notes the familiar end-result. Another person concentrates his interest on a different link in the chain of events to which he, in turn, assigns the cause for the identical final occurrence. The symptomatic similarity is obvious to all. The confusion of etiologic standpoints has been caused by the narrowness of vision.

Despite the steady succession of rejected theories of shock, we must not despair of obtaining sooner or later a clearer conception of the underlying pathology. It is a distinct step in advance to be able to assert what shock is not. The nervous system has been relegated to an inferior rôle, at best, in the newer attempts at an explanation. It would seem that the theory of fat embolism as a prominent predisposing cause may also be set aside¹ as secondary in moment. At present greater interest is being centered in certain chemical factors which may underlie many, if not all, types of shock. To understand their possible significance we must recall the now admitted underlying manifestations. Circulatory collapse may occur in spite of arterial constriction; in this a diminution of the output of the heart is a prominent factor, if not the sole cause. Such fall of the cardiac output occurs almost invariably, however, without any considerable impairment of the activity of the heart. It is not a primary failure of this organ. The systolic output fails because the diastolic filling is inadequate. The arterial blood has lost in volume and is not to be found accumulated in the heart or great veins; but it finds its way into the peripheral vessels of the abdominal viscera and skeletal muscles. An added feature, long recognized and described as a characteristic feature of shock, is the

fall of effective blood volume due to the loss of plasma. As the fluid leaves the blood, the corpuscular content consequently increases.

In studying the action of histamin, which produces symptoms resembling in many ways those of traumatic and surgical shock, Dale and Laidlaw² call attention to the characteristic features. There is an oligemia, partly due to passage of plasma out of the blood vessels, partly to retardation of the flow of blood at the periphery. They believe the evidence to favor the view that this is due to a general loss of tone by the capillaries throughout the body. The excessive permeability of these vessels, which allows escape of plasma, is regarded as a further stage of the same type of action. Histamin applied locally in very small doses causes redness, swelling and the formation of an edematous wheal.³ Dale and Laidlaw make the interesting comment, in relation to such mild inflammatory reactions to a chemical substance, that the widening of the capillary lumina, the opening up of channels normally empty, the transudation of plasma through abnormally permeable endothelium, and the tendency to stasis of the concentrated blood—these phenomena, when occurring in an area so restricted that the general arterial pressure is not materially affected, will produce the familiar sequence of redness, swelling and edema. Large doses, on the other hand, produce something more than local effects. The circulatory collapse may be regarded as the outcome of a more widespread poisoning of the capillary endothelium depending on the mode of application or the magnitude of the dose.

According to the view just mentioned, certain chemical substances can thus be responsible for either local inflammation and edema or the more widespread circulatory collapses seen in shock. Histamin is a compound with which both sorts of phenomena can be effected. If we conceive of the liberation of a comparable substance into the circulation as the result of tissue injury (traumatic toxemia) or damage to viscera (surgical shock), an analogy is promptly afforded. Anaphylactic shock may be interpreted, on this hypothesis, to be the outcome of physical changes in endothelial cells leading to relaxation of their tone and ultimately to abnormal permeability. The shock-like symptoms occasionally following administration of arsphenamin may also depend on an acute endothelial intoxication. The common factors in all the cases are a poison and an altered capillary permeability. Whether and how such endogenous poisons actually enter the circulation remains to be demonstrated. At any rate our attention is temporarily diverted from the nervous system to the blood vessels and chemical agencies in the attempt to elucidate the genesis of shock.

THE NEW INDUSTRIAL PHYSIOLOGY

The necessity of conserving the health of the working man and woman has long been regarded as a part of the public health program. The recognition of certain diseases as indisputably occupational has resulted in establishing corresponding schemes of vocational hygiene. The well-being of the worker has been the keynote of such endeavors. The measures instituted have tended toward the elimination of accident and other health hazards in the trades. The problems have been approached from medical, social and, in lesser degree, economic points of view. Protective legislation and education have paved the way for progress. The war, which has called for unexpected speeding up of industrial performances in many fields of production, has emphasized a somewhat different feature of the human machine. In order to be in a position to work efficiently, in the industrial sense, not only health and strength must be conserved but the physiologic mechanism must also be allowed to act to the best advantage. Fatigue factors must be taken into account in relation to the output of work as well as to the conservation of the health of the worker. The needs and limitations of an intricate combination of living organs and tissues with their chemical and nervous regulations must be taken into account. These newer physiologic aspects of industrial activity have created problems for study to which Lee¹ has given the name "industrial physiology." By this is designated "the sum of knowledge pertaining to the working of the human mechanism in industrial activity, and it thus includes psychological phenomena as well as those more technically recognized as physiological." We may expect to hear much more in the near future of the new studies which have as their object the scientific need of learning how the industrial worker actually performs his work and what the conditions are under which he can work most efficiently and can produce the largest output, while at the same time maintaining his body in health and in the best working condition. The practical objects of industrial physiology are to establish in all working places the conditions which conduce at the same time to the maximum output and the maintenance of the maximum power of the worker.

THE PRODUCTION OF MEDICINAL PLANTS IN THE UNITED STATES

Under the stimulus of war-time needs there was a revival and an extension of backyard gardening in the United States. Neglected plots of land were cultivated and made to yield some contribution to the country's store of food. No one can estimate with any accuracy what the extent of this production was, but it undoubtedly represented a considerable increment to the food supply and a wholesome addition to the variety of diet under times of stringency in the food market. This impetus to individual gardening will probably continue to produce results for some years to come. Stimu-

lated by a heralded shortage of medicinal plants, suggestions have occasionally been made toward the augmentation of the supply of botanical drugs by similar modes of individual effort. Cushman¹ has, however, sounded a warning relative to this laudable ambition. The production of medicinal herbs in America, he asserts, depends largely on the labor cost, and can be made a profitable enterprise only when it is conducted on a scientific basis and on a sufficiently large scale to absorb the high cost of labor involved in the tilling, planting, cultivating, harvesting, curing and packing operations. At the same time, the drug grower faces an uncertain and precarious market for his wares, for, although his drug plants are needed, the need is strictly limited, and the slightest overproduction is either entirely unsalable or salable at a price less than the cost of production. But this is not the only obstacle to individual initiative on the part of uninformed growers. Crude botanical drugs must meet certain pharmacopeial standards that involve special chemical or biologic tests. Cushman asserts that unless a producer is able to hold his belladonna to an assay at least twice as strong as the U. S. P. requirement, it would not be worth producing at all under American conditions. Crude drugs of such high potency can be obtained only by the application of trained scientific knowledge to the problem. To the extent that the growing of medicinal plants is to become an agricultural feat rather than the haphazard gathering of wild forms, scientific considerations must go hand in hand with the practical procedures.

HONORARY DEGREES IN PUBLIC HEALTH

THE JOURNAL has already commented on the encouraging tendency to standardize degrees in public health work that is being manifested by several universities interested in the training of various kinds of public health experts.² It hardly needs argument to convince one that if, as is highly desirable, certificates and degrees in public health are to be regarded as necessary prerequisites to official positions, then a considerable measure of uniformity in training and experience must be correlated with the holding of a specific degree. This is generally recognized by the teachers in public health work in this country. It is somewhat disquieting, therefore, to find that certain educational institutions are conferring an "honorary" degree with exactly the same titles—such as doctor of public health—that are elsewhere given only for a comprehensive course of study and research. It is evident that, unless this practice can be checked, hopeless confusion will result in the public mind as to the real significance of degrees in public health. One reason why the Ph.D. degree has so high a standing in our educational system is that it is never given as an honorary degree by any reputable university. Unless degrees in public health can be made to stand likewise for definite academic training and achievement, it is

1. Cushman, A. S.: Growing Medicinal Plants in America, *J. Heredity* 10: 32 (Jan.) 1919.

2. Standardization of Degrees in Public Health, *Current Comment*, *J. A. M. A.* 72: 941 (March 29) 1919.

plain to see what fate will overtake them. If honorary degrees are to be given in public health, they should have a specific and unambiguous nomenclature. Meritorious public health workers should accept no other.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending June 27, there were 13,144 officers in the Medical Corps, a decrease of 321 from the previous week. The Medical Corps contained 2,715 officers. The total number of physicians discharged since the beginning of the war is 19,097. The records of the discharge branch of the general staff show the following discharges of officers of the Medical Department from Nov. 15, 1918, to noon, June 26, 1919: 2 brigadier-generals, 55 colonels, 404 lieutenant-colonels, 1,994 majors, 8,023 captains, 9,952 lieutenants, making a total of 20,430 officers discharged to date. Nov. 15, 1918, there were 30,591 medical officers on duty; June 26, 1919, there were 10,161 officers on duty in the Medical Corps.

Appointments in Army Medical Service

Col. Walter D. McCaw and Lieut.-Col. Robert E. Nolle, both of the Medical Corps, have been recommended by the President to the senate for appointment as assistant surgeon-generals with the rank of brigadier-general in the medical department of the United States Army, from March 5, 1919. The senate has not yet acted on these recommendations but will do so in executive session shortly. The following officers, now first lieutenants in the Medical Officers' Reserve Corps, have been recommended by the President for appointment as first lieutenants in the Medical Corps of the Regular Army: Earl Hazelton Hare, Robert Effinger Cumming, Thomas Mathew Calladine, Jr., William Davis Gill, Harvey David Thornburg, Charles Smith Moss and Irwin Bradford Smock. These recommendations are now before the senate and will be acted on shortly.

Retirement of Members of the Nurse Corps

A bill authorizing the retirement of members of the Army Nurse Corps (female) has been introduced by Congressman Julius Kahn of California, chairman of the House Committee on Military Affairs. The measure provides that members of the Army Nurse Corps who have had active service therein for twenty years, including time served as contract nurses, shall on application to the Secretary of War, be placed on a retired list and shall thereafter receive 75 per cent of the pay, exclusive of foreign-service pay, which they were drawing at the time they became entitled to retirement on completion of the required twenty years' active service. As the author of this bill is chairman of the military committee of the house, it is expected that he will get early and favorable action on it.

Recognition of Members of Draft Boards

Suitable recognition for members of the medical advisory draft boards is provided for in three measures recently introduced in Congress. A bill introduced by Senator Henderson of Nevada authorizes the President to award brevet commissions and suitable medals to the physicians who assist in the draft. Senator Randall of Louisiana has introduced a similar measure, as has Congressman Kahn of California, but the Randall and Kahn measures do not provide brevet commissions. In addition to appropriate medals, the thanks of Congress are extended. It is fully expected that one of these measures will be passed at this session, but it is not believed likely that brevet commissions will be favored.

Bill to Provide Hospital Care for Government Employees

All Army and Navy hospitals would be open to civilian employees of the government when the employees are suffering with tuberculosis, under the terms of a bill introduced by Senator Sheppard of Texas.

Organization for Providing Scholarships in American Universities for French Students

Major Leonard D. Frescohn, now at the Besancon University in France, writes that, at the completion of their courses, a number of delegates from the fourteen universities of France, attended a meeting in Paris, May 28, and as an expression of thanks for the interesting work given to the American soldiers in French universities, it was agreed to found fourteen scholarships, enabling fourteen Frenchmen to study for one year in America.

Army Surgeons Decorated

JAMES H. KEELING, Captain, M. C., U. S. Army, Albany, N. Y., who has been on duty with the British Forces for twenty-one months, has been decorated twice by the king.

HARVEY FRASER, West Salem, Wis., has been awarded the Italian Distinguished Service Medal for work overseas.

Colonel Seaman Cited

GILBERT E. SEAMAN, Colonel, M. C., U. S. Army, Milwaukee, formerly chief surgeon of the Thirty-Second Division, has received a personal letter from General Pershing commending him for his work as division surgeon overseas, and expressing his appreciation of the valuable services rendered to the American Expeditionary Forces as division surgeon and later as corps surgeon of the Sixth Army Corps.

Awards of Distinguished Service Medal

The distinguished service medal has been awarded by the commanding general, American Expeditionary Forces, to the following named British and French civilians:

DOCTEUR COUSSERGUE. For exceptionally meritorious and distinguished services. As médecin régulateur at St. Dizier he rendered the American Expeditionary Forces valuable service in making possible the evacuation of the forward areas during the St. Mihiel and Argonne offensives. When the number of American hospital trains available were found insufficient, he placed at our disposition the facilities of the French. Laboring personally, day and night, in order that there might be no interruption of the service.

M. MOIRIER. For exceptionally meritorious and distinguished services. As a member of the French government and the civilian chief of the Medical Department of the French Army, he placed all available of his great department, both in material and personnel, at the disposal of the American Expeditionary Forces. His advice was of great value, aiding us in the solution of many problems, and he rendered services of inestimable value in assisting us in securing proper evacuation and hospitalization for the sick and wounded.

The distinguished service medal has been awarded by the commanding general, American Expeditionary Forces, to the following named officers of the American Expeditionary Forces:

WILLIAM J. CROOKSTON, Colonel, Medical Corps, United States Army, Pittsburgh, Pa. For exceptionally meritorious and distinguished services. As division surgeon he displayed marked ability of organization and administration throughout the service of the Twenty-Eighth Division in France. With keen judgment he supervised the location of dressing stations and field hospital and used remarkable discretion in directing the entire work of evacuation of a large number of casualties. By constant vigilance and unceasing effort he provided for the health and treatment of the troops with whom he served, displaying professional attainments of a high order.

WILLIAM L. KELLER, Colonel, Medical Corps, United States Army. For exceptionally meritorious and distinguished services. As director of the professional services, Medical Department, American Expeditionary Forces, he displayed marked ability in the organization and assignment of the forces at his disposal for hospital care at the front and in the rear areas. He was discerning in his knowledge of conditions, using his insufficient personnel to the maximum advantage in relieving the suffering of our sick and wounded, and in obtaining prompt treatment for battle casualties. His comprehensive grasp of the problems which presented themselves resulted in the saving of many lives.

THOMAS L. RHODES, Colonel, Medical Corps, United States Army. For exceptionally meritorious and distinguished services. As division surgeon of the Eightieth Division, he had charge of the Medical Department's work of that unit throughout its combat activities. Due to his skillful administration, it functioned smoothly and with precision at all times, caring promptly for a large number of the sick and wounded. As chief surgeon of the First Corps, and later of the First Army, he displayed executive ability of high order, being constant and zealous in devotion to his arduous tasks.

ALBERT P. CLARK, Lieutenant-Colonel, Medical Corps, United States Army. For exceptionally meritorious and distinguished services. As medical representative on, and later as General Staff member of, the first section, General Headquarters, American Expeditionary Forces, he displayed sound judgment and wide comprehension of existing conditions in the management of ocean tonnage allotments, and devised

and efficiently operated a system of supply for the Medical Department of the American Expeditionary Forces. Largely through his personal efforts, energy and foresightedness the difficulties in the procurement and shipment of medical supplies for the sick and wounded were successfully overcome.

JOSEPH F. SILER, Colonel, Medical Corps, United States Army. For exceptionally meritorious and distinguished services. He has been in charge of the Laboratory Services of the American Expeditionary Forces. Due to his untiring zeal and professional attainments, he has been able to render invaluable service in the prevention of the spread of infectious disease among our troops. Under his valuable instructions, medical officers were sent out equipped to handle the new medical and surgical problems of war in a manner not believed possible before the present war.

JAMES D. FIFE, Colonel, United States Army. For exceptionally meritorious and distinguished services. In command of Base Hospital No. 24, he served with distinction with the British Expeditionary Forces. He was later assigned to duty in the office of the chief surgeon in charge of hospital planning and construction, procurement of permanent buildings, establishment of hospitalization, liaison with the French authorities, the General Staff and with the Engineers. In the performance of these multifarious duties he displayed conspicuous ability.

PIATT ANDREW, Lieutenant-Colonel, United States Army. For exceptionally meritorious and distinguished services. Coming to France at the beginning of the war, he showed remarkable ability in organizing the American Field Service, a volunteer service for the transportation of the wounded of the French armies at the front. On entry of the United States into the war, he turned over the efficient organization he had built to the United States Army Ambulance Service, and by his sound judgment and expert advice rendered invaluable aid in the organization of that organization. To him is due in a large measure, the credit for the increasingly valuable work done by the light ambulances at the front.

JOSEPH M. FLINT, Lieutenant-Colonel, Medical Corps, United States Army, New Haven, Conn. For exceptionally meritorious and distinguished services. When placed in a position of great responsibility as commanding officer of Mobile Hospital No. 29, at Aulnois-sur-Vertuzey, France, he used extraordinary skill and sound judgment in the organization and operation of that unit, the first of its kind in the American Expeditionary Forces. In its formative period he was faced by great and unforeseen difficulties, but with untiring energy and genius he surmounted all obstacles, making his unit a model for all those subsequently organized.

NATHANIEL ALLISON, Colonel, Medical Corps, St. Louis, Mo. For exceptionally meritorious and distinguished services. As chief of the orthopedic work in the zone of the Army, he personally directed, in a most conspicuous and painstaking manner, splinting and orthopedic work, which resulted in the saving of many lives and greatly relieved suffering among our wounded.

CHARLES M. FOX, Captain, M. C. U. S. Army, Chicago, on duty with the Three Hundred and Fifty Third Infantry, for extraordinary heroism in action. Gassed near Bouthéville, France, Oct. 26, 1918, Captain Fox maintained his battalion dressing station under a terrific bombardment of gas and high explosive shells, which almost demolished his station. He quit only when blindness made it impossible for him to work.

Honors to Officers

HARRY N. KERNS, Major, M. C., U. S. Army, evacuation officer at the port of embarkation, has received a decoration from the mayor of Langres, France, in recognition of his services in assembling and organizing Base Hospital 53, which rendered such distinguished service in and around Langres.—**DR. WILLIAM J. MAYO**, Rochester, Minn., has been awarded the congressional medal of honor, with the following citation:

"**DR. WILLIAM J. MAYO**, formerly Colonel, U. S. Army, for exceptionally meritorious and conspicuous service, in addition to manifold service to the Surgeon-General by furnishing needed advice and counsel, he distinguished himself by exceptionally meritorious service to the government in his work in the organization of the surgical service and his invaluable assistance in the reorganization of the medical department on the scale demanded by the war."

The mayor of Langres also presented **WALTER E. FOLEY**, Lieut. M. C., U. S. Army, Davenport, Iowa, with the French Tri-Color and Coat of Arms of the city in appreciation of his service in relieving and ministering to the needs of the city of Langres and in recognition of medical care and treatment given to about 300 French wounded.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

NOTE.—In the following list, L. signifies Lieutenant; C., captain; M., major; L. C., lieutenant-colonel; and Col., colonel.

To Walter Reed General Hospital, D. C., from Camp Lee, Lieut. J. D. GILLIS, Wauwatosa.

Wyoming

To Denver, Colo., from Letterman General Hospital, Capt. O. K. SNYDER, Cheyenne.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

DISTRICT OF COLUMBIA

New Roentgenologists for Garfield Hospital.—Drs. Thomas A. Groover and Arthur C. Christie have been appointed roentgenologists on the staff of Garfield Hospital to succeed Dr. Walter H. Merrill, whose resignation takes effect July 1.

Renewal of an Ancient Charter Sought.—An item in THE JOURNAL for June 28 mentions a bill introduced in the House of Representatives by Mr. Lazaro of Louisiana providing for the incorporation of the Medical Society of the District of Columbia and conferring the power to own and convey real estate. The caption of the item stated that the bill incorporates a new medical society; this is incorrect as the real purpose of the bill is to secure the historical continuity of a charter originally granted by the national Congress, Feb. 16, 1819, the bill of incorporation having been signed by President James Monroe. A new charter, with some emendations, was granted by Congress, July 7, 1838, the act being signed by President Van Buren. Both of these charters conferred on the society the right and duty of electing a medical licensing board, the sole guardian of the standards of medical practice in the District of Columbia until 1896 when a board of medical supervisors for the District of Columbia was provided by Act of Congress. Since the original charters imposed on the society the duty of examining and licensing physicians, they forbade the society to establish a tariff of charges or fees; when, therefore, the function of the society as a licensing body was abolished on the one hand, and on the other the society in 1913 took on the function of a component unit of the American Medical Association, these old charters lapsed. It is now sought to revive the corporate identity of the society by congressional action, and the incorporators named in the bill are the members of the executive committee for the current year, it being impracticable to name the 365 members of the society in a bill of incorporation. The power to own and convey property is sought by the society because of the intention to erect a home for the organization in the near future; an energetic and highly successful campaign is now going forward which should result in the erection of a \$75,000 building this fall.

ILLINOIS

Illegal Practitioner Arrested.—Ernest M. Sparks of Casey was arrested by an inspector of the Department of Registration and Education of the State of Illinois and fined \$284 for practicing "Suggestive Therapeutics" in violation of the medical practice act.

Personal.—Dr. C. St. Clair Drake, director of the State Department of Public Health, Springfield, was elected secretary-treasurer of the Conference of State Health Authorities at its annual meeting in Atlantic City, and was also made secretary of the executive committee of health authorities of the United States.—Dr. A. B. Taylor, Canton, has been elected county physician of Fulton County.

Chicago

Illegal Practice Charge.—A. G. Dillenbaugh is said to have been taken into custody June 20, by an inspector of the Department of Registration and Education charged with practicing medicine without a license.

Clinic for Discharged Soldiers.—The new clinic established at Mercy Hospital for discharged soldiers and sailors and their dependents, which has been equipped at an expense of \$35,000 by the National Catholic War Council, was opened June 25.

Sanatorium Auditorium Opened.—The new auditorium building erected at the Municipal Tuberculosis Sanatorium, at a cost of \$100,000, was formally opened June 28. The dedicatory exercises were held June 29. Dr. William M. Harsha, superintendent of the institution, presided and addresses were made by Drs. John Dill Robertson and William A. Pusey and others.

Home from Overseas.—Gustavus M. Blech, Lieut. Col. M. C. U. S. Army, who went overseas as assistant division surgeon of the Thirty-Third Division, was then in command of a base hospital at Autun, France, and later was commanding officer of a large base hospital in France, returned to Chicago, June 29.—William H. G. Logan, Col. D. C. U. S. Army, has returned after more than two years of military service, and has resumed practice.—Kalph S. Porter, Lieut.-Col. M. C. U. S. Army, division surgeon of the Twenty-Sixth Division and also on duty with the First and Second Divisions overseas, reached New York on his return home, June 26.

Personal.—Dr. Frank Billings has been discharged from military service and has returned to Chicago.—Dr. H. Gideon Wells has reached Chicago from Roumania where he did administrative public health work. There is much typhus and smallpox in Roumania, largely accounted for because the army has been mobilized, taking most of the physicians from civil practice.—Dr. Charles M. Robertson has been discharged and has resumed practice.—Dr. Walter W. Armstrong of the health department has been made city health officer of La Crosse, Wis.—Joseph D. Purvis has been made chief director of the Hahnemann Medical College and Hospital, for a term of five years, succeeding Dr. Clarence V. Clemmer.

KENTUCKY

Premedical Work Required. The Kentucky State Board of Health has adopted as a requirement for application for licensure, two years of premedical work. This rule becomes effective in 1922.

Tablet Unveiled.—Appropriate exercises at the unveiling of the memorial tablet to the late Dr. Charles O. Zahner, professor of physiology in the University of Louisville, took place in the college building, June 26.

Founders' Day Dinner.—Founders' day dinner exercises were celebrated under the auspices of the Louisville Alumni Association of Vanderbilt University, at the Pandemonium Club, Louisville, May 24. Dr. John A. Witherspoon, Nashville, Tenn., delivered the principal address.

Personal.—Drs. John Walker Moore, McConnellsville, S. C., and Larren R. Ellars, National Military Home, Ohio, have been elected full-time teachers in medicine and surgery, respectively, in the University of Louisville. They will reside in the hospital and will direct the work of the resident intern staff, and the bedside teaching of the medical classes.—Dr. Granville S. Hanes, Louisville, will soon leave for England and France, where he will take up special research work on the cancer problem.—Dr. Thomas C. Holloway has been discharged from the Medical Corps, U. S. Army, after service overseas, and has returned to Lexington.

MARYLAND

Volunteers of America to Establish Hospital.—Arrangements have been completed for the establishment of an emergency hospital by the Volunteers of America in Baltimore. A four-story brick structure has been secured and the work of remodeling will start immediately, so that the hospital will be open by October 1.

For Quarantine Station.—Acceptance of the Baltimore Quarantine Station by the government at the price of \$176,775 is provided for in the sundry civil bill, which has been reported to the Senate by Senator Warren, chairman of the Appropriations Committee. This bill authorizes the secretary of the treasury to acquire the station to be operated as one of the adjuncts of the public health service.

Site for Tuberculosis Sanatorium Selected.—The directors of the Maryland Tuberculous Sanatorium have closed their option on the property adjoining Endowment Sanatorium at Towson, this property to be used as a site for a tuberculosis sanatorium for the colored people, as provided by the last legislature. The tract comprises 50 acres of undeveloped property. The directors of the institution expect to make the new sanatorium the first of a series to be erected throughout the state for the treatment of colored people suffering from the disease. Because of the prevalence of this disease among the negroes in Maryland, it is declared that the establishment of such an institution as is proposed will be a protection to Towson, rather than an inconvenience.

Personal.—Henry R. Carter, Major, M. C., U. S. Army, has obtained his discharge from the Army and will shortly return to his home at the U. S. Marine Hospital in Baltimore. —Harry C. Schmeisser, Major, M. C., U. S. Army, professor in the department of pathology in the Johns Hopkins University, has arrived in the United States after fourteen months' service with the U. S. Army in France. —William J. Coleman, Major, M. C., U. S. Army, Baltimore, former superintendent of the University Hospital, who has been serving with the American Expeditionary Forces, has been promoted to the rank of lieutenant-colonel and is stationed at Coblenz, Germany. —Dr. Alma S. Rotholz, Baltimore, of the Johns Hopkins Hospital, who was engaged by the Red Cross to work among the children of the war-ridden territory under the direction of Dr. William F. Lucas, Sykesville, and while in France acted as resident physician at a hospital for children at Havre, France, has returned to her home in Baltimore. —N. Morland Owensby, Major, M. C., U. S. Army, Baltimore, who has been stationed at the base hospital, Camp Gordan, Ga., for several months, has been discharged from the service and will locate in Atlanta. —At the recent commencement exercises of the University of Georgia, Augusta, the honorary degree of doctor of science was conferred on Dr. John M. T. Finney, Baltimore.

MASSACHUSETTS

Personal.—George F. Keenan, Major, M. C., U. S. Army, Brighton, has been promoted to lieutenant-colonel, and has been transferred to the staff of the chief surgeon at Le Mans, France. —Drs. Edward H. Bradford and Frederick C. Shattuck, both of Boston, have been elected members of the board of overseers of Harvard University.

Memorial Building for City Hospital.—A three-story building to be known as the Thorneycke Memorial and to be devoted to research work in pathology is to be erected at the Boston City Hospital during the summer, at a cost of more than \$200,000, in memory of the late Dr. William H. Thorneycke, Boston. The new building will be erected in the rear of the medical laboratory in the hospital grounds.

MICHIGAN

Correction.—In the June 7 issue of THE JOURNAL it was erroneously noted that the annual meeting of the Michigan State Medical Society was held in Bay City. The meeting was held in Detroit.

Personal. Dr. William R. Grant, Lyons, who has been ill for a long time, after examination in the probate court, June 7, was taken to the Traverse City State Hospital for treatment. Dr. James A. King, postmaster of Manistee for more than five years, has resigned.

MISSOURI

Laboratories Discontinued.—The laboratories at the state board of health office have been discontinued and the work of these institutions has been assumed by the department

of preventive medicine laboratories of the state university, Columbia.

Personal.—Dr. M. J. Armstrong, Springfield, has been elected assistant physician and bacteriologist at the Missouri Sanatorium, Mount Vernon. —Dr. Harry LaRue, Dexter, suffered a second cerebral hemorrhage and is reported to be in critical condition.

Division of Child Hygiene Established.—The recent legislature passed a bill creating a division of child hygiene in the state department of health and giving the state board of health general supervision and regulation of the physical inspection of public schools in the state.

Communicable Disease Law Passed.—At the last session of the legislature, a law was enacted giving the state board of health authority to promulgate and enforce adequate rules and regulations for the control and prevention of communicable diseases. This enables the board to comply with the requirements of the interdepartmental social hygiene board. Active cooperation will begin, July 1. The state receives \$35,808 as its allotment.

Resolutions Against Venereal Diseases.—At the annual meeting of the Missouri State Medical Association, held at Excelsior Springs, May 26 to 28, resolutions were adopted setting forth that the Missouri State Board of Health on account of lack of funds is handicapped in its cooperation with the United States Public Health Service in the conduct of a vigorous campaign against venereal disease by its inability to arrange the provision of facilities for free laboratory examinations of specimens and the diagnosis of venereal disease, to furnish free arsphenamin for indigent cases, and to adopt a policy for clinics and free treatment. The association endorsed the campaign being waged by the United States Public Health Service, and especially that part of the campaign which provides facilities for the diagnosis and treatment of venereal disease, calling on physicians in the state to cooperate with the health authorities in their efforts to combat venereal disease, and urging that the local authorities in the larger cities of the state provide for the establishment of clinics in cooperation with the state board of health.

NEW YORK

Personal.—Dr. Edward S. Godfrey of Albany has returned from France, where he has been connected with the American Red Cross in the capacity of chief of health inspection service.

Clinton County Increases Public Health Facilities.—The board of supervisors has provided a public health nurse, a school nurse and a tuberculosis and venereal clinic at Plattsburg; a school nurse at Chazy; a visiting nurse at Ausable Forks and at Lyon Mountain a county tuberculosis nurse.

New York City

Mount Sinai Prepares to Build.—Plans have been filed with the building department for an eight-story addition to Mount Sinai Hospital, on Fifth Avenue between Ninety-Ninth and One Hundredth streets. The estimated cost of the proposed addition is \$500,000.

NORTH CAROLINA

Hospital for High Point.—Several High Point physicians are planning for the construction of a new hospital to cost with equipment, \$75,000, and to be of fireproof construction throughout.

Hospitals Made Permanent.—U. S. Army General Hospital No. 19, Oteen, near Asheville, is announced as a permanent hospital and a new lease has been negotiated with the owners for the continued use of the Kenilworth Hotel which was taken over early in the war for the use of the hospital. The U. S. Military Hospital at Azalea, it is also understood, will be continued permanently for the care of tuberculosis patients.

Personal.—Davidson College at the recent commencement conferred the degree of LL.D. on Dr. John Peter Monroe of Charlotte, formerly president of the North Carolina Medical College and of the North Carolina State Medical Society.

Dr. Claude L. Pridgen, Wilmington, delivered the principal address at the annual North Carolina state masonic picnic at the State Masonic Orphan Asylum, Oxford, June 23.

OHIO

Summer School at Sanatorium.—Twenty-five physicians of the state registered for a special two weeks' course in the treatment of tuberculosis at the State Sanatorium, Mount Vernon.

Clinic as Soldiers Memorial.—The memorial of Summit County to soldiers in the World War, will it is expected, be in the form of a health clinic building and fund. This building will be in memory not only of the men from Summit County who died in the World War, but also of those who died in the Spanish-American War and the Civil War.

Personal.—Dr. Ora O. Fordyce, superintendent of the Athens State Hospital, will, it is announced, be transferred to the Toledo State Hospital, July 15, succeeding Dr. George R. Love, whose resignation takes effect on that date.—Dr. T. Addison McCann, Dayton, has been appointed a member of the state medical board.—Dr. Mary A. Wilson, Delaware, for six years chief medical officer of the Delaware Girls Industrial School, has resigned.—Dr. Lot H. Hughes, for twenty-five years local surgeon of the Pennsylvania system at Denison, has resigned and has been succeeded by Dr. Edmund A. Wolfe.

Decision Regarding Venereal Disease.—The Hamilton County Common Pleas Court in a case in which the constitutionality of the venereal disease regulations of the state were attacked has upheld the regulations. The case was a habeas corpus proceeding brought by an alleged prostitute who had been held by the Cincinnati Health Department as a person reasonably suspicious and who, being found infected, had been placed under quarantine as provided by the state regulation. The release of the petitioner was demanded on the grounds that she was deprived of liberty on suspicion and that she had not been granted trial by jury. In dismissing the case the court stated that the health authorities had as clear a right to quarantine persons afflicted with venereal disease as to quarantine a person exposed to smallpox or scarlet fever, and that the question of jury trial was not concerned in the case, as the petitioner was not held on a criminal charge.

PENNSYLVANIA

Doctors' Licenses Revoked.—The licenses of seven physicians who violated the drug act have been revoked according to an announcement made, June 27, by the State Bureau of Medical Education and Licensure. The board has also suspended five other medical men and revoked for three months the license of Dr. Elizabeth M. Baer, Philadelphia, now serving a sentence for sedition.

Personal.—Dr. George K. Strode, Harrisburg, has been appointed assistant chief health inspector of the department of health of Pennsylvania.—William H. Leifler, Capt., M. C., McKeesport, has been cited for bravery by Marshall Petain in the name of the French government. He received the Croix de Guerre, April 13, and was made regimental surgeon of the Twenty-Third Infantry.

Power for Health Board.—The senate passed finally the house bill broadening the powers of the commissioner of health and the advisory board under the quarantine act of 1915. Under the bill the commissioner of health, with the approval of the advisory board, may determine what are communicable diseases and provide for the quarantine of such diseases. This law was found necessary after the difficulty encountered in the influenza epidemic of last fall. The act also enables the department of health to carry out its venereal campaign in a conservative manner.

Philadelphia

Personal.—O. H. Perry Pepper, Major, M. C., U. S. Army, who is at a base hospital in France, has been promoted to lieutenant colonel.—Robert G. LeConte, Lieut.-Col., M. C., U. S. Army, who went to France with the Methodist Hospital Unit, and was naval consultant for Pershing's forces, has been made a chevalier of the Legion of Honor.—George M. Coates, Col., M. C., U. S. Army, who was commanding officer of Base Hospital No. 50 up to the time the armistice was signed, following which he went to Dijon and St. Agillon as an ear, nose and throat specialist, has returned home.—Dr. Thomas C. Stellwagen is winning a plucky fight for his life which he has been making for a number of weeks in a private hospital in Media, where he has undergone five operations for an infection contracted while operating with a movable unit in France.—The senate confirmed the appointment of John D. McLean as deputy commissioner of health.

UTAH

State Medical Board Organizes.—At the meeting for organization of the Utah State Board of Medical Examiners, Dr. David C. Budge, Logan, was elected president; Dr.

Frederick E. Straup, Bingham, vice president, and Dr. George F. Harding, Salt Lake, secretary-treasurer.

Personal.—John F. Sharp, Lieut. Col., M. C., U. S. Army, Salt Lake City, division surgeon of the Fortieth Division, and later of the Sixth Division of the American Expeditionary Forces in France, returned home, June 10.

Community Clinic Opens.—The free community clinic and dispensary, Salt Lake City, financed by the business and professional men of Salt Lake City, was formally opened, June 2. Six physicians are on duty daily at the clinic, and any church, lodge, or charitable organization is privileged to send persons needing and unable to pay for medical attention.

CANADA

University News.—A tablet was recently unveiled in the New Medical Building, McGill University, to the memory of nine medical students who lost their lives in France. Dr. George E. Armstrong, acting dean of the medical faculty, delivered an address as the tablet was unveiled.—Prof. J. George Adami, McGill University, is to leave that institution to accept the vice chancellorship of Manchester University, England.

Personal.—Dr. William A. Harvie, returned from overseas with the Saskatchewan Hospital Unit, has recovered his health and resumed practice in Regina.—Dr. Harvey Clare, assistant superintendent of the Hospital for the Insane, Toronto, and superintendent of the Toronto Detention Hospital, has been appointed a general medical officer superintending all the hospitals for the insane and acting in an advisory capacity to the provincial secretary.

Free Medical Course to Overseas Men.—Speaking at the banquet in Quebec last week given by the Quebec physicians to the delegates to the Canadian Medical Association annual meeting, the president, Dr. Groulx, stated that arrangements had been made whereby Laval medical department offered a free course in study to young Canadian doctors who had been overseas. In return the English universities in Canada would be asked to extend similar privileges to French-Canadians in any part of Canada.

Hospital News.—The members of the medical staff of the Regina General Hospital have advised the governors that a new wing for the treatment of the sick is advisable rather than a new residence for the nurses of the institution.—The Sisters of the Grey Nuns Hospital, Regina, Sask., have decided on a new wing for their institution.—The hospital board of the Winnipeg General Hospital is planning a yearly clinic week to which physicians from all parts of western Canada will be invited. It is also proposed to establish an interns' alumni society to bring former members of the house staff together.—The Winnipeg General Hospital is opening a psychopathic ward which is to be in charge of Dr. Alvin T. Mathers, supervisor of the psychopathic department at Johns Hopkins.—Saskatchewan has selected Weyburn as the site of the proposed mental hospital created by the government of that province. Dr. Robert M. Mitchell, speaker of the Saskatchewan assembly, has been appointed the superintendent of the hospital. The cost of the institution has been \$1,000,000. It will have a capacity of 1,600 beds when completed.

GENERAL

Drop Germans from Membership.—The American Surgical Association, at its annual meeting in Atlantic City, June 17, voted unanimously to drop all German and Austrian honorary fellows from its roll of membership.

Psychoanalysts Meet.—The ninth annual meeting of the Psychoanalytic Association was held in Atlantic City, June 20. In the absence of the president, Dr. G. Stanley Hall, Worcester, Mass., Dr. Smith Ely Jelliffe, New York City, presided. The following officers were elected: president, Dr. Abraham A. Brill; vice president, Dr. Horace W. Frink; and secretary-treasurer, Dr. William A. White, all of New York City.

Medical Librarians Hold Meeting.—The twentieth annual meeting of the Medical Library Association was held in Atlantic City, June 9, under the presidency of Dr. William Browning, Brooklyn. The object of the association is to foster the medical libraries and the maintenance of an exchange system. Any medical society, association, university or college having a fixed home and a library of not less than 500 volumes, with a librarian in charge, is

eligible for membership. The annual dues for library membership are \$10, and for individual membership, \$5.

New Regulations Governing the Sale of Alcohol.—The Bureau of Internal Revenue on June 30, issued regulations governing the sale of alcohol for medical purposes. The regulations state that "Physicians may prescribe wines and liquors for internal use or alcohol for external use, but in every such case each prescription shall be in duplicate and both copies be in the physician's handwriting." The quantity prescribed for such a patient in a given time shall not exceed 1 quart. In no case shall a physician prescribe alcoholic liquors unless the patient is under his constant supervision. All prescriptions must indicate clearly, the patient's name, street address, and apartment number, if any, the date when written, the condition or illness for which prescribed and the name of the pharmacist to whom the prescription is to be presented. Similar detailed restrictions for the sale of alcohol by drug stores have also been promulgated.

Additional Research Appropriations.—At a meeting, June 20, the United States Interdepartmental Social Hygiene Board approved applications for appropriations from its scientific research fund "for the purpose of discovering . . . more effective medical measures in the prevention and treatment of venereal diseases," as follows:

YALE UNIVERSITY MEDICAL SCHOOL

1. (a) "Effect of anilin dyes, particularly gentian violet on the gonococcus with reference to the growth of the organism in media containing the dye, and with reference to the effect on organisms in tissue (therapeutic effect)." Under the direction of Joseph M. Flint, M. D., and John W. Churchman, M.D., Professors of Surgery.

(b) "An intensive study of methods for the isolation and identification of the gonococcus with a view to the determination of the homogeneity or heterogeneity of strains and their etiological relationships." Under the direction of George H. Smith, M.D., Assistant Professor, Department of Pathology and Bacteriology.

(c) "The demonstration of syphilitic nature of unusual lesions encountered at the postmortem table." Under the direction of Milton C. Winternitz, M.D., Professor of Pathology and Bacteriology.

UNION UNIVERSITY MEDICAL DEPARTMENT, ALBANY

2. "For studies on the nature of the Wassermann reaction." Under the direction of Thomas Ordway, M.D., Dean and Associate Professor of Medicine.

The United States Interdepartmental Social Hygiene Board is composed of: Carter Glass, Secretary of the Treasury; Newton D. Baker, Secretary of War; Josephus Daniels, Secretary of the Navy; Lucien G. William F. Snow, Medical Corps, U. S. A.; Lieut. Col. Joseph R. Phelps, Medical Corps, U. S. N.; Asst. Surg.-Gen. Claude C. Pierce, U. S. Public Health Service, and Thomas A. Storey, Executive Secretary.

Up to June 21, the Board had approved appropriations from its Scientific fund for twenty researches distributed among twelve medical schools.

Rockefeller Foundation and Epidemics.—The review of the work of the Rockefeller Foundation for 1918 tells of the development of its efforts to eradicate malaria and yellow fever from certain districts. In four towns in Arkansas anti-mosquito work was carried out with marked success, and the result was a reduction in malaria cases of 97.4 per cent. as compared with 1916, and an antimalarial campaign was also carried out in Mississippi with the cooperation of the board of health of that state.—Major-Gen. William C. Gorgas, formerly Surgeon-General of the United States Army, and, after his retirement, director of the yellow fever work of the International Health Board, has just returned from a trip to South America in an endeavor to determine the seed-beds of yellow fever, and institute systematic measures to destroy the disease at its source.—On account of a yellow fever epidemic in Guatemala, in June, 1918, the International Health Board tendered its services to the president of Guatemala, and sent Dr. Joseph H. White, U. S. P. H. S., recently released from the Army and granted leave by the Public Health Service, to Guatemala, where he established quarantine, drafted physicians into service, and so placed well-tested measures for the control of yellow fever in effect that the epidemic was brought promptly under control.

In June of last year a commission was sent to Guayaquil, Ecuador, for the study of, and to record information regarding the sanitary condition of Ecuador, and the bacteriologic, chemical and clinical aspects of yellow fever. Measures for yellow fever control were actively inaugurated in Ecuador, Nov. 27, 1918, and by the end of December, twenty-five squads of five men each, were systematically engaged in the destruction of the stegomyia mosquito.

Mortality Statistics.—The annual compilation of mortality statistics by the U. S. Census Bureau for the death registration areas in the continental United States for 1917, shows

that during the year, 1,068,932 deaths occurred, equivalent to a death rate of 14.2 per thousand. Of these deaths fully one third were due to heart disease, pneumonia and tuberculosis; another third to nephritis, cerebral hemorrhage, cancer, diarrhea and enteritis, arterial disease, influenza, diabetes, diphtheria and bronchitis. The death registration area at this time included twenty-seven states, the District of Columbia, and forty-three cities in nonregistration states, with a total population of about 75,000,000. The general causes of deaths were as follows: heart disease, 115,337, or 15.3 per hundred thousand; pneumonia, 112,821, or 14.9 per hundred thousand; tuberculosis, 110,285, or 14.6 per hundred thousand; nephritis, 80,912, or 10.7 per hundred thousand; cerebral hemorrhage, 62,431, or 8.2 per hundred thousand; malignant disease, 61,452, or 8.1 per hundred thousand; diarrhea and enteritis, 59,504, or 7.9 per hundred thousand; arterial disease, 19,055, or 2.3 per hundred thousand; influenza, 12,975, or 1.7 per hundred thousand; diabetes, 12,750, or 1.6 per hundred thousand; diphtheria, 12,453, or 1.6 per hundred thousand; bronchitis, 12,311, or 1.6 per hundred thousand; typhoid fever, 10,113, or 1.3 per hundred thousand; measles, whooping cough and scarlet fever, 31,723, or 2.8 per hundred thousand, and external causes, 81,953, or 10.8 per hundred thousand. The chief causes of accidental deaths were in order, falls, railroad accidents and injuries, burns, automobile accidents and injuries, accidental drowning, and accidental asphyxiation, vehicles, street cars, machinery and insulation. The suicides for the year were 10,050, or 1.3 per hundred thousand, and the deaths from other external causes, including homicide, 10,053, or 1.3 per hundred thousand. The death causes that show a decrease as compared with 1916, are: heart disease, pneumonia, diarrhea and enteritis, malignant disease, influenza, diabetes and typhoid fever. Death causes showing an increase are: tuberculosis, nephritis, cerebral hemorrhage, arterial diseases, diphtheria, bronchitis, measles, whooping cough and scarlet fever.

FOREIGN

Maternity and Infant Welfare Schemes.—The National Association for the Prevention of Infant Mortality and for the Welfare of Infancy (4 and 5, Tavistock Square, London, W.C.1.) held a national conference on infant welfare as part of the National Baby Week celebrations, at the Kingsway Hall, Kingsway, London, W.C.1, July 1 to 3, under the presidency of the Rt. Hon. Christopher Addison, M.P., M.D. The following subjects were discussed: (a) Antenatal and neonatal mortality and its prevention; (b) the work of the midwife in relation to antenatal and neonatal mortality; (c) the industrial employment of mothers in relation to infant mortality; (d) the illegitimate child.

RIO DE JANEIRO LETTER

RIO DE JANEIRO, June 7, 1919.

Sporadic Case of Yellow Fever in Rio de Janeiro

In the month of May a case of yellow fever occurring in a patient coming from the state of Bahia on a Brazilian steamer was reported. The patient was immediately isolated and died the next day. Strict measures were taken to prevent the spread of the disease. No new case has been reported.

Eradication of Yellow Fever in the Northern States of Brazil

The federal government, in agreement with the state authorities, has sent sanitary commissions to the states of Bahia, Alagoas, Sergipe and Ceará, with a view of exterminating yellow fever in these states. Since Emilio Ribas and Oswaldo Cruz succeeded in stamping out this disease in São Paulo and in Rio de Janeiro, respectively, similar work has been carried on with good results in Amazonas, Pará and Espírito Santo.

There remain still five other states in the north of Brazil in which yellow fever is endemic and to which the government will send experts of the federal staff in order definitely to eradicate the disease. When this work is done, Brazil can be considered free of yellow fever.

Session Held in Honor of Prof. Miguel Pereira

The National Academy of Medicine, the oldest medical association in Brazil, held a session, May 31, in honor of M. Pereira, lately deceased. The secretary of the interior presided. Three addresses were delivered landing the late member as physician, writer and professor. Miguel Pereira was one of the most brilliant speakers of his day. He was a

horn fighter, and his slogan "Brazil is a vast hospital" still rings throughout the land.

As a rallying cry it accomplished much good, although it may be considered an exaggeration, for soon after its adoption the government took the first steps to combat various endemic diseases, such as malaria and hookworm disease. Miguel Pereira was comparatively a young man, being only 46 years of age when he died, Dec. 23, 1918.

Death of João Florença Gomes

Influenza has claimed another victim among the physicians of Brazil. João Florença Gomes, late assistant of the Instituto de Butantan, São Paulo, died of influenza the last week in May. He was a brilliant member of the institute and his works on serpents are well known in scientific circles. It was his purpose to go to the United States to study pathologic anatomy at the Rockefeller Institute for Medical Research.

Rural Sanitation in Minas and Acre

The government has divided the territory of Acre into four divisions. To each one a medical commission has been assigned in order to combat malaria and hookworm, all expenses being paid by the government. The same service was initiated in the state of Minas, the federal government paying one third of the expenses.

Scientific Works of Dr. Adolpho Lutz

Dr. Adolpho Lutz has published an interesting work on Brazilian fresh water snails of the genus *Planorbis*, intermediate hosts of trematode parasites of man and animals (*Schistosomum mansoni*). The author gives a list of other Brazilian and South American species as found in literature, giving descriptions and drawings. A key to aid in distinguishing Brazilian genera is included. Six new species are described.

In the company of Dr. Oswino Penna, Dr. Adolpho Lutz made an excursion to the north of Brazil collecting notes on *Schistosomum*. During the journey notes of 312 coprologic examinations were taken. Of the 312 specimens examined, seventy-one contained eggs of *Schistosomum*, giving an average of 22.75 per cent.

MADRID LETTER

MADRID, April 15, 1919.

Retirement of Medical Professors and Hospital Physicians

The government has adopted new regulations relative to the retirement of government employees. The many abuses and the favoritism shown in deciding the age at which any particular employee should be retired, caused the adoption of new regulations according to which professors will retire at 71 years of age. Among the prominent physicians to whom the new regulations will apply, are Dr. Florenço de Gastros, the well known surgeon; Dr. Hldefonso Rodríguez, professor of the history of medicine in the University of Madrid, and Dr. Antonio Chacón, the famous gynecologist. The same law has been extended to embrace the public assistance physicians and, as most of the hospitals in Madrid belong to this department, one of those who have to give up their positions is Dr. Huertas, a physician of great repute in Spain.

Compulsory Vaccination in Madrid

It is interesting that in our country law-making bodies seem to have foreseen every little detail neglected in countries having the most advanced legislation to such an extent that our codes seem model ones from many viewpoints, although on account of the national apathy many of the laws remain unenforced. This happened with the provisions enacted a long time ago for the prevention of smallpox. Vaccination was compulsory and was enforced in the large cities for young children but revaccination was only practiced by the higher classes. Most of the rural population neglected to vaccinate themselves in spite of all recommendations. The result has been that smallpox was so prevalent among the poorer classes as to constitute a disgrace for the capital and since vaccination was not enforced in the neighboring provinces and revaccination was neglected among most of the people at Madrid, smallpox was constantly ravaging the masses of the population, especially store employees, servants, workmen, etc., and during the last decade, in addition to the usual outbreaks, we have had three serious epidemics, the last one last winter. When smallpox was most prevalent recently, Don Leopoldo Romeo, a newspaper man and great admirer of the United States, was appointed governor of the province of Madrid. He formed the resolution

of ending the constant menace of smallpox and ordered the enforcement of the laws that made vaccination and revaccination compulsory and which had been neglected so far. It was enough to threaten people with the imposition of fines to have everybody at Madrid either vaccinated or revaccinated. Two physicians of the so-called "naturopaths" went to the governor protesting against the vaccination regulations. The governor, after listening to them, fined them each 500 pesetas (\$100) for opposing the enforcement of the law and inducing others to oppose it and, in addition, threatened them with another fine if they resisted vaccination. The two propagandists decided that it was better to be vaccinated than fined and followed the general example. In the San Juan de Dios hospital, where the smallpox patients are attended, these have numbered 300.

An Itch Outbreak

Madrid has been struggling with a small outbreak of itch which has been the result of another undertaking of the governor. One of the characteristics of which Madrid is not very proud, in spite of its picturesque, are the *pobres* (beggars) who, until not so long ago, filled in such great numbers practically every city and village of Spain. The mayors of some towns, Santander, Seville and others, determined to put an end to this type of professional beggar that shows his rags with a sort of pride, exhibits his sores and bothers passers-by with his entreaties. As a result, the beggars disappeared from those towns but in Madrid our authorities have, it seems, been so busy with other things that they could not attend to this matter. From time to time, some enterprising official has rounded up all the beggars, but this has been done under such unfortunate circumstances that everybody feared to read news to this effect since outbreaks of typhus fever have followed, on two occasions, the crowding of beggars in places lacking the necessary sanitary conditions. One of these outbreaks ended only when it exhausted itself after attacking more than 1,000 people. The last of these beggar roundings-up has been followed by results not so serious, since it has just caused the spread of itch, giving some more work to the physicians and nurses of the above-mentioned San Juan de Dios hospital which was one of the first established in the world for skin and venereal diseases. The worst part of the whole happening was that there arose a question of jurisdiction between the governor who ordered the gathering of the beggars and the police authorities who had no place to keep their charges and were therefore compelled to release them. As a result the campaign came to an end and the beggars flourish now more than ever, practically everywhere, with more complaints than ever and prouder, if that can be, of their poverty and their sores. Cervantes, Mateo Alemán, Quevedo and other classical writers can find followers among modern authors for their models of beggars and hoboes are still a thing of the day in the life of Madrid.

A Sanitary Campaign

Four physicians of noble aims are carrying out a sanitary campaign with the greatest enthusiasm. Dr. Cortezo, the former minister and president of the Royal Academy of Medicine and editor of the *Siglo Veintiuno*; Dr. Francisco Rodríguez, former minister and journalist; Dr. Recasens, dean of the School of Medicine of Madrid, the most famous gynecologist of Spain and physician to the queen; and Dr. Juarros, the psychiatrist and writer, have united in this enterprise and are traveling from town to town where any hygienic question may arise or some danger may exist to the public health or some sanitary improvement may be made, giving conferences in practically every public place as part of a campaign of propaganda of hygienic ideals which may tend to the betterment of the race and to avoid epidemics and suffering. They have shown that the people may become interested in questions which are not political and the loftiness of their purposes has served to attract first the curiosity of the people and then their interest so that they have been now joined by persons belonging to all the political parties and many others who are not in politics and belonging to all social classes.

The Death of Dr. Francisco Cortezarena

Dr. Francisco Cortezarena, first president of the Royal Academy of Medicine, has died rather suddenly at the age of 84 years. For a few hours before his death he was still at the club as usual, talking with those present. One could say of him that he was the representative of the glorious past of medicine, as he always took part at the end of the most bitter medical debates to call attention to the history of our science and make people feel that even the most recent and destructive medical theories were nothing but new labels for

forgotten doctrines, and his personal manner was so charming and engaging that it pleased the two sides and convinced even the most rabid partisans. His autobiography is a model of its kind, and all those interested in medicine in the last part of the 19th century will have to resort to it as he made a careful note day after day of everything he either did himself or witnessed. He was for a time director general of public health and was also a member of the senate, where he took part in the enactment of the modern sanitary legislation. For many years he was a professor in the School of Medicine of Madrid where all the present teachers take pride in calling themselves his pupils.

LONDON LETTER

LONDON, June 11, 1919.

The Ministry of Health and the Control of Nostrooms

In the House of Lords the lord chancellor, according to his promise, mentioned in my last letter, moved an amendment to the ministry of health bill that the ministry should be responsible for prosecutions for "patent medicine" frauds. The amendment provides that the ministry shall "take all such steps as may be desirable to secure the carrying out of measures for the avoidance of fraud in connection with alleged remedies of diseases." The lord chancellor said that "patent medicine" frauds could, under the existing law, be attacked only on the charge of obtaining money by false pretenses. These were very difficult prosecutions, and more often than not failed. The course which ought to be adopted was to strengthen our legislation, and in this connection he reminded the house of the recommendation of the select committee on "patent medicines" in 1914: "Your committee further recommends the following legislative enactments: 1. That every medicated wine, and every proprietary remedy containing more alcohol than that required for pharmacologic purposes, be required to state on the label the proportion of alcohol contained in it. 2. That the advertisement and sale (except the sale by a physician's order) of medicines purporting the cure of the following diseases be prohibited: cancer, consumption, lupus, deafness, diabetes, rupture (without operation or appliance). 3. That all advertisements of remedies for diseases arising from sexual intercourse or referring to sexual weakness be prohibited. 4. That all advertisements likely to suggest that a medicine is an abortifacient be prohibited." These recommendations had quite recently been discussed by the government, and the lord chancellor was authorized to say that the government concurred in them. A very early attempt would be made to carry out in a separate bill these specific recommendations.

The Vivisection of Dogs

The strong medical opposition organized against the bill for the prevention of vivisection of dogs has proved effective. It may be remembered that the bill prohibited any experiment of a nature calculated to give pain or disease to any dog for any purpose whatever, either with or without anesthetics. The government amendment excepts cases in which for reasons specified in the certificate the experiment would necessarily be frustrated unless it is performed on a dog, and no other animal is available for such an experiment. The undersecretary for the home department said that the object of the bill was the absolute prohibition of experiments on dogs, but the amendment would give an additional precaution and further supervision of all experiments on this animal and so make it impossible, as indeed it already was, to inflict on a dog during the course of any experiment anything but the most limited and short-lived pain. The government, while prepared to protect the few dogs experimented on, was not prepared to go against the overwhelming mass of experience and scientific opinion and prohibit absolutely experiments on dogs. Under the existing act, the great majority of the operations on dogs were simply inoculations or the cutting of small veins which did not in the majority of cases interfere with the comfort or health of the dog. When a severe operation was to be performed, the application for a license was referred to a committee of seven of the most distinguished scientific men. A series of drastic conditions dealing with the antiseptic treatment of wounds was laid down. The amendment was carried by 147 to 69 votes, and the title of the bill was altered from "A Bill to Prevent the Vivisection of Dogs" to "A Bill to Impose Further Restrictions on the Vivisection of Dogs."

War Census of Medical Students

At the opening of the summer session of the General Council of Medical Education, the president, Sir Donald Mac-

alister, gave returns showing the number of students taking courses of instruction. They were: October, 1917, 7,048; May, 1918, 7,630, and January, 1919, 9,490. Between May, 1918, and January, 1919, the first-year students had increased from 2,043 to 2,907, as compared with 1,480 registered in 1913. The junior students had thus practically doubled since the year preceding the war. But the students in the final year of their curriculum numbered only 936 men and 222 women, or barely enough to supply to the register the normal increment of newly qualified practitioners during the current year. First-year students who were on service have returned to the schools in almost overwhelming numbers for the summer session. The accumulated freshmen of a succession of years, whose first year's course was broken by the summons to military service, together with a number of educated men and officers entering for the first time on the medical curriculum with subsidies from the government, have flooded the schools and taxed severely their accommodation and their teaching staff. With the object of giving all practicable facilities to men who have fought for their country, equipment has been improvised and temporary instructors have been provided. At some centers it has even been necessary to refuse admission to normal students proceeding in the ordinary course from secondary schools to schools of medicine. Some of the difficulties felt this summer in dealing with numbers so far above the average will no doubt be lightened in the following years, as the professional schools are able to readjust their arrangements; but they cannot all be surmounted without heavy expenditure, and it may be that the state will have to lend substantial assistance to enable these institutions to meet the needs of ex-service students. In any case it seems certain that within five years' time the depletion in the ranks of the profession caused by the war will be much more than made good.

American Graduates in London

The emergency graduate course instituted by the Fellowship of Medicine (described in previous letters) has proved very successful. A meeting of more than 100 American medical officers attending the course has been held to form an association in appreciation of the facilities afforded to them. Combined efforts to familiarize their countrymen with the exceptional clinical facilities offered by the London medical schools and hospitals were agreed on. An American medical graduates' society is to be founded in London for the benefit of American physicians visiting the British Isles, and also to foster the present cordial relations between the medical profession of the two countries. Mr. Philip Franklin, F.R.C.S., a London otologist and laryngologist who is an American citizen, has been elected honorary president, and Lieut.-Col. S. C. Gurney, U.S.M.C., president.

Vital Statistics for 1917

The report of the registrar-general for 1917 has just been issued. The figures are of course much influenced by the war. The total civilian population of England and Wales was estimated to be 14,085,300 males, and 19,625,700 females. The marriages number 258,855, giving the lowest rate yet recorded. The births numbered 608,340, being 117,174 fewer than in 1916. The birth rate again shows a fall for some years, and this is continued. In 1913 the rate was 24.1 per thousand; 1914, 23.8; 1915, 21.9; 1916, 20.9; 1917, 17.8. The 1917 rate is almost exactly 50 per cent. of the rate for the decennium 1871-1880, the rate prevailing before the downward trend. The death rate was 14.4 per thousand; corrected to the 1901 standard population, the standardized rate was 13.5. A lower rate has been recorded only twice; but if allowance is made for the deterioration of the civilian population, owing to military selection, it is probable that the rate for 1917 is not inferior to that of any other year. The child mortality was low. The number of deaths per thousand births of children under 1 year was 90. For the first time the number of deaths due to typhoid fever was less than 1,000 (977). The death rate from other infectious diseases was low. That from tuberculosis was 13 per cent. greater than in 1913. This is attributed to the dietetic restrictions of the war, particularly the deprivation of fats. Deaths attributed to cancer, 41,158, give the highest rate yet recorded. Taking the interval of nineteen years from 1897-1918 to 1916-1917, the mortality from accessible cancer has increased 50 per cent. among males, while inaccessible cancer has increased only 41 per cent. Hence the increase cannot be explained by improved diagnosis. The mortality from alcoholism has decreased, which is attributed to the restriction in the output and sale of alcoholic liquors during the war.

Marriages

MICHAEL FRANCIS CLAFFEY, Lieut., M. C., U. S. Army, Naugatuck, Conn., on duty at U. S. General Hospital No. 12, Biltmore, N. C., to Miss Helen Delpire of Chicago, at Asheville, June 30.

CARL ALEXANDER WEST, Lieut., M. C., U. S. Army, Columbia, S. C., on duty with the American Expeditionary Forces in France, to Mlle. Odette Voirin of Bar-le-Duc, France, May 10.

JOHN W. WHITEHEAD, Lieut., U. S. N. R. F., Algiers, Ind., to Miss Bernice Hobbs of Hillsboro, Ind., at Jasper, Ind., June 10.

WILLIAM JAMES BASLER, JR., Mont Alto, Pa., to Miss Mathilda O. Tejge of Philadelphia, at Hummelstown, Pa., June 18.

WEBSTER WHITALL BELDEN, Capt., M. C., U. S. Army, to Miss Martha Hall Hennen, both of New York City, recently.

SAMUEL ARTHUR VAN OSDEL to Miss Clara Millow, both of Johnson, Neb., in New York City, recently.

J. H. EUGENE ROSAMOND, Memphis, Tenn., to Miss Inez Fennell of Walnut Hills, Cincinnati, June 7.

JAY HERBERT WALLAHAN to Miss Ruth Marsh, both of Corning, Iowa, at Des Moines, June 4.

GEORGE WENDELL DUNLAP, Toledo, Ohio, to Miss Mary A. Jacobson of Chicago, May 31.

HENRY MORGAN WINANS to Miss Judith Terrell Hawley, both of Denver, recently.

JAMES STANLEY WILLIAMS to Miss Ruth Huss, both of Massillon, Ohio, June 7.

JOHN FRANKLIN CONNER to Miss Emma Ehrhardt, both of Sidney, Ohio, June 2.

KESHAVA DEVA SHASTRI to Miss Minnie Jensen, both of Omaha, June 4.

Deaths

William Hugh Carroll * Passaic, N. J.; New York University, New York City, 1884; aged 58; visiting surgeon to the Passaic General Hospital, and to the Passaic Home and Orphan Asylum; once president of the Passaic County Medical Society; for four years a member of the state board of health; one of the founders of the New Jersey Surgical Society and of the Passaic General, and St. Mary's hospitals; died in the Passaic General Hospital, June 20, from heart disease.

Rolla M. Chase, Bethel, Vt.; Baltimore Medical College, 1890; aged 62; a member of the Vermont State Medical Society; also a graduate in dentistry; once president of the state dental society and chairman of the state board of dental examiners; first president of the Bethel Electric Light and Power Company and vice president of the Bethel Shoe Company; for three years a member of the local school board; died at his home, June 10, from nephritis.

Arthur Brigham Norton, New York City; New York Homeopathic Medical College, New York City, 1881; aged 62; professor of ophthalmology in his alma mater from 1902 to 1907; oculist to the Hahnenann and Laura Franklin Free hospitals; for thirty-five years surgeon to the New York Ophthalmic Hospital; founder and for ten years editor of the *Homeopathic Eye, Ear and Throat Journal*; died at his home, June 18, from pneumonia.

John T. Nagle * New York City; New York Medical College, New York City, 1864; aged 77; a member of the American Public Health Association; for thirty years an official of the health department of the city of New York; registrar of records of the health department of the city of New York and later chief of the bureau of municipal statistics; assistant surgeon, U. S. Army, during the Civil War; died at his home, June 14.

Hugh Forbes McGaughey * Winona, Minn.; College of Physicians and Surgeons in the City of New York, 1890; aged 45; one of the best known surgeons of Southern Minnesota; local surgeon of the Northwestern and Burlington system; died in Tacoma, Wash., June 20, in an ambulance in

which he was being taken from a Tacoma hospital to the Western Washington Hospital for the Insane, Steilacoom.

Frederick Wallace Abbott, Taunton, Mass.; Eclectic Medical College of Maine, Lewiston, 1886; aged 58; associate editor of the *Massachusetts Medical Journal* from 1894 to 1904, and of the *American Medical Journal* since 1906; professor of medical history and medical ethics in the Middlesex College of Medicine and Surgery, Boston; died at his home, June 19, from the effects of an accident five months before.

Richard Ewell Brown * New York City; New York University, New York City, 1894; aged 49; a fellow of the New York Academy of Medicine; attending surgeon to the Lying-In Hospital, New York City, from 1897 to 1905; assistant attending physician to the Manhattan Maternity Hospital; a specialist in obstetrics; died at his home, June 14, from cerebral hemorrhage.

William A. Cusick, Salem, Ore.; Willamette University, Salem, Ore., 1867; aged 81; a member of the state legislature in 1885 and 1886; a member of the first faculty of his alma mater; for two years surgeon in the army; for several years consulting physician at the State Hospital, and for five years physician to the state penitentiary; died at his home, June 16.

Thomas H. Tomlinson, Plainfield, N. J.; University of Pennsylvania, Philadelphia, 1859; aged 82; a member of the State Medical Society of New Jersey; who celebrated his golden wedding, Dec. 30, 1918; dean of the medical fraternity of Plainfield; a member of the original staff of Muhlenburg Hospital; died at his home, June 22, from pneumonia.

Clarke Storer Gould * Norwood, Mass.; Harvard Medical School, 1888; aged 55; who served during the war as captain, M. C., U. S. Army, at Camp Sherman, Chillicothe, Ohio, and was honorably discharged, Dec. 27, 1918, died in the Peter Bent Brigham Hospital, Boston, March 28, from general septicemia following a cellulitis of the neck.

James F. Jones, Sherman, Texas; University of Texas, Galveston, 1899; aged 46; a member of the State Medical Association of Texas; for two years assistant surgeon of the Mexican Central Railway; died in St. Vincent's Sanitarium, Sherman, June 12, as the result of injuries sustained in a grade crossing accident, June 9.

Walter Keene Wilkins, New York City; Bellevue Hospital Medical College, 1880; aged 66; assistant physician at the Ward's Island Insane Hospital from 1887 to 1890; who was convicted on June 27, of the murder of his wife; committed suicide by strangulation in the Nassau County Jail, Mineola, N. Y., June 29.

Ralph H. Watkins, Wolcott, N. Y.; University of Syracuse, N. Y., 1883; aged 58; a member of the Medical Society of the State of New York; at one time coroner and health officer of Wayne County; died in the General Hospital, Rochester, N. Y., June 18, after an operation for cerebral tumor.

N. Fred Essig * Spokane, Wash.; University of Pennsylvania, Philadelphia, 1868; aged 70; formerly president of the Washington State Board of Health; a member of the National Association of Railway Surgeons; died in the Mayo Brothers' Hospital, Rochester, Minn., June 8, from nephritis.

Joseph Mark Doyle, Brooklyn (license, New York, 1882); aged 55; for nineteen years connected with the Queens County Department of Health and for many years of the Kings County Inebriate Home; died at his home, June 17, three weeks after a surgical operation.

Jacob W. Coblentz, Fort Wayne, Ind. (license, Indiana, 1897); aged 80; whose license is said to have been revoked for fraud; died in a store in Fort Wayne, June 18, from the effects of cyanide of potassium, self-administered, it is believed, with suicidal intent.

T. E. McBrayer, Shelby, N. C.; College of Physicians and Surgeons, Baltimore, 1879; aged 79; a member of the Medical Society of the State of North Carolina, and a prominent physician of western North Carolina; died at his home, June 25, from carcinoma of the liver.

Leon J. Willien * Terre Haute, Ind.; Washington University, St. Louis, 1867; aged 78; one of the founders of St. Anthony's Hospital, Terre Haute, and for several years president of the staff; surgeon to St. Mary's Institute; died in St. Anthony's Hospital, June 17.

Alfred M. Adsit * Hastings, Minn.; Columbus (Ohio) Medical College, 1881; aged 62; physician to the Hastings State Hospital; died in St. Joseph's Hospital, St. Paul, June 17, after an operation for appendicitis and the removal of gallstones.

* Indicates "Fellow" of the American Medical Association.

Milford Bard Shipp, Jr., Salt Lake City; Jefferson Medical College, 1891; aged 52; died in the Latter Day Saints Hospital, Salt Lake City, June 11, from the effects of a gunshot wound inflicted by a patient in an altercation over treatment.

Rosavelle Gardner Philip, Stamford, Conn.; Woman's Medical College of the New York Infirmary for Women and Children, New York City, 1875; aged 72; a member of the Connecticut State Medical Society; died at her home, June 11.

Meverell Knox Allen, Louisville, Ky.; University of Louisville, Ky., 1867; aged 72; once health officer of Louisville; medical director of the Intersouthern Life Insurance Company; died at his home, March 13, from arteriosclerosis.

David John Jones, Youngstown, Ohio; Rush Medical College, 1897; aged 52; formerly coroner of Columbia County, Ohio; died in Youngstown, June 16, from injuries sustained in a collision between his automobile and a street car.

Daniel Tucker McCall, Rome, Ga.; Medical College of Georgia, Augusta, 1872; aged 72; a Confederate Veteran; once physician of Floyd County, Ga., and a member of the Rome school board; died at his home, June 11.

Thomas W. Walker * Steubenville, Ohio; Western Reserve University, Cleveland, 1889; aged 53; local surgeon to the Panhandle system, and surgeon to the Gill Hospital; died at his home, June 11, from cerebral hemorrhage.

Edward Hottle, Philadelphia; Jefferson Medical College, 1874; aged 71; for more than forty years employed by a firm of manufacturing chemists in Philadelphia; died at the home of his daughter in Wayne, Pa., June 8.

Henry Fowler Stowell, Rochester, N. Y.; College of Physicians and Surgeons in the City of New York, 1877; aged 71; a specialist in diseases of the eye and ear; died at his home, June 8, from senile debility.

Daniel Ross, Denison, Texas; Missouri Medical College, St. Louis, 1891; aged 54; a member of the State Medical Association of Texas; died in Harris, Mo., April 1, from cerebral hemorrhage.

Cornelius Augustus Ahearn, Lynn, Mass.; Harvard Medical School, 1866; aged 78; a member of the Massachusetts Medical Society; died at his home, April 16, from lobar pneumonia.

John Albert Crum, Marion, Mo.; Beaumont-Marion Sims Hospital Medical College, St. Louis, 1890; aged 51; died in St. Mary's Hospital, Jefferson City, Mo., April 4, from diabetes.

Edward Monroe McCoy, Huntersville, N. C.; North Carolina Medical College, Charlotte, 1894; aged 47; formerly city physician of Charlotte; died at his home, June 4, from heart disease.

William Clark Black, Tulsa, Okla.; Starling Medical College, 1890; aged 50; died in Tulsa in March, death being due to suicide while despondent on account of ill health.

Emil E. Nussle, Chippewa Falls, Wis. (license, Wisconsin, 1899); aged 66; a practitioner since 1874; died in St. Joseph's Hospital, Chippewa Falls, June 7, from heart disease.

Vandalier N. Swan, Maywood, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1877; aged 71; died in the Oak Park (Ill.) Hospital, June 24, from septicemia.

Joseph J. Noeker, Detroit; Georgetown University, Washington, D. C., 1902; aged 42; who never practiced on account of ill health; died at his home, June 11.

Stephen L. Williams, Spring Garden, Ill.; American Medical College, St. Louis, 1879; aged 80; died at his home, June 4, from cerebral hemorrhage.

James D. McDonald, Clayton, Mich.; Cincinnati College of Medicine and Surgery, 1869; aged 78; died at his home in March from organic heart disease.

George Edwin Day, D.D., New York City; a graduate in medicine; aged 85; died at the home of his son in New York City, April 7, from heart disease.

Andrew J. Stovall, Jr., Sour Lake, Texas; University of Louisville, Ky., 1882; aged 62; died at his home, May 29, from cerebral hemorrhage.

Lloyd Arnold Jones, Hamilton, Ont.; University of Toronto, Ont., 1911; aged 31; died at his home, March 1, from pneumonia following influenza.

Charles Dodd Brewer, Springfield, Mass.; College of Physicians and Surgeons in the City of New York, 1882; aged 71; died at his home, June 3.

Chester Jackson McBride, Welland, Ont.; University of Toronto, Ont., 1909; aged 33; died at his home in March from pulmonary tuberculosis.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

THE ALLIED MEDICAL ASSOCIATIONS OF AMERICA

Another Rocket in the Pyrotechnics of Quasi-Medical Organizations

It was once said, in the days when diploma mills flourished, that it seemed easier to start a "university" than it was to open a grog shop. A study of quasi-medical organizations convinces one that it is easier to found a "medical society" than it is to establish a peanut stand. Most reputable practitioners of medicine who care to affiliate themselves with medical organizations are members of the American Medical Association, its component societies, or similar scientific bodies. It is not surprising, then, that those who live and move in the twilight zone of professionalism, from visionaries riding bizarre medical hobbies to those who have special interests to exploit, should create and make use of hybrid medical organizations. Such organizations multiply with the fecundity of rabbits. They flourish for a while, obtain more or less newspaper and other publicity—usually more, because of the sensational methods of those controlling them—then, having served the purpose of those who brought them into being, they lapse into innocuous desuetude.

The official *accouchement* of the Allied Medical Associations of America occurred, according to that organization's report, May 18, 1918. On the official stationery of the Allied Medical Associations of America in use in May, 1919, we find the names of the "Officers," "Censors," etc. These constitute, presumably, the more prominent members of this organization. We give briefly, some data regarding some of these so that a rational perspective may be obtained:

L. M. OTTOFY, M.D., St. Louis, Mo.—Dr. Ottofy seems to have been the chief organizer, if not, indeed, the founder. He has been its "Secretary-Treasurer" since its inception; he is also "editor" of its journal. Ottofy, according to our records, was born in 1865 at Budapest, Hungary, and was graduated in 1888 by the Homeopathic Medical College of Missouri. In Polk's Medical Directories for 1914 and 1917, Ottofy has those extended notices which any physician can obtain who cares to pay for it. According to these notices, Ottofy is, or has been, affiliated with the following "societies":

President of the International Cancer Research Society.
Ex-President of the St. Louis Society of Medical Research.
Second Vice-President of the Missouri Institute of Homeopathy.
General Secretary of the American Association of Progressive Medicine.
Chairman of the Board of Censors of the Missouri Institute of Homeopathy.
Member of the American Institute of Homeopathy.
Member of the Southern Homeopathic Association.
Member of the American Association of Clinical Surgeons.
Member of the Southern Homeopathic Medical Society.
Member of the Kansas City Society of Medical Research.
Honorary member of the Chicago Society of Medical Research.

In December, 1911, numerous newspaper clippings show that Dr. Ottofy was obtaining much publicity relative to his antivaccination activities. At that time the papers reported that Ottofy was suing the St. Louis Board of Education for \$25,000 damages, because the Board would not admit to the schools of the city a child he had "internally" vaccinated. In November, 1913, the *St. Louis Republic* reported that Ottofy had claimed to have discovered a serum for the cure of cancer, and quoted Ottofy as claiming "a record of 72 per cent. of cures" in "selected cases." In February, 1914, the newspapers reported that Ottofy was making a trip east "on the trail of radium for use in his practice in the cure of cancer" and quoted him as stating: "I have learned on good authority that there is radium in Missouri,

and just where I refuse to divulge at this time." In January, 1915, the *St. Louis Republic* reported that Otfoty, at a meeting of the "St. Louis Society of Medical Research," had announced that he had perfected a serum treatment for cancer, which "is curing patients who have been pronounced incurable by so-called 'cancer experts.'" In January, 1916, the *St. Louis Star* reported that Otfoty had sought an injunction against the Board of Education of St. Louis to restrain it from using its funds for "the maintenance of a Board of Hygiene." In July, 1916, *St. Louis* papers recorded that Otfoty, who was then running for coroner, had been cited to appear before the Prosecuting Attorney to explain a charge of passing out, at a political meeting, a card alleged to have borne an indecent drawing of President Wilson. The Prosecuting Attorney was said to have instructed Otfoty to bring the plates from which the cards were printed to his office. Two days later the papers stated that Otfoty had sent the cards and plates by messenger to the prosecuting attorney's office.

IGNATZ MAYER, M.D., Detroit, Mich.—Mayer, "President" of the organization, according to our records, was born in Austria in 1860, and was graduated by the Medico-Chirurgical College of Philadelphia in 1894. Mayer, according to advertisements that have appeared in Detroit papers, is a "registered physician and surgeon specializing exclusively in the cure of rupture without detention from occupation." The Mayer advertisements have notified the ruptured of Detroit and vicinity (*via* Detroit newspapers) that hernia keeps one down in health and earning capacity and "there is no need for this. I have cured over 4,000 patients in twenty years continuous practice in the cure of rupture."

N. LA DOTT JOHNSON, M.D., Chicago.—Dr. Johnson's name appears as the "First Vice-President" of the Allied Medical Associations of America. A few years ago, Dr. Johnson's name also appeared as the "Dean of the Faculty" of the "American Post Graduate School." This "school" was a mail-order concern which, according to the "Annual Announcement," would grant diplomas and confer degrees as follows: "Master of Surgery," "Bachelor of Medicine," "Bachelor of Science," "Master of Electro-Therapy," "Doctor of Osteopathy," "Doctor of Psychology," "Master of Massage," etc.

H. M. GOEHRING, D.O., M.D., Pittsburgh, Pa.—The "Second Vice-President," according to the letterheads of the "Association" carries the letters D.O., M.D., after his name. So far as our records show, and they are most complete and based on official data, H. M. Goehring is an osteopath, but not a doctor of medicine.

A. E. ERLING, M.D., Milwaukee, Wis.—A. E. Erling, according to the stationery, is "Chairman" of "Censors." Our records fail to show that Erling ever graduated in medicine. The Health Department of Milwaukee, however, says that Erling, when interviewed, claimed to have "a diploma from the German Medical College of Chicago, but refused to show or present the same." The American Medical Directory has this item:

German Medical College, Chicago. Chartered Dec. 28, 1891,
by Johann Malok. Fraudulent. Extinct.

A few years ago Erling was in La Crosse, Wis., and in 1908 a circular letter bearing his name and picture was sent out from which the following extracts are taken. Capitalization as in the original:

"Dear Friend:—Permit me to call your attention to the fact that Dr. A. E. Erling, the eminent specialist, after many years of travel, practice and medical research, has given up his extensive road practice and severed his connection with the several medical institutes which have heretofore occupied considerable of his attention. Dr. Erling's success in the treatment of all CURABLE DISEASES is truly remarkable. NERVOUSNESS, ALL BLOOD DISEASES, BILEMIAISM, DISEASES PECULIAR TO WOMEN, CATARRH, DEAFNESS, CHRONIC CONSTIPATION, . . . APPENDICITIS . . . FILES, STOMACH TROUBLES, PARTIAL PARALYSIS, etc., give way as if by magic under his skillful method of treatment. . . . Understand please, that Dr. Erling DOES NOT ACCEPT A CASE FOR TREATMENT unless he can PROMISE A SPEEDY AND POSITIVELY PERMANENT CURE."

THE JOURNAL also has in its files advertisements (vintage of 1915), from some Wisconsin country newspapers, which

notify the afflicted that "Drs. Erling and Karass, the expert German Specialists" could be seen in their offices in the "Schlegel Hotel," the "Schlitz Hotel," etc., as the case might be. Whether one of these "German Specialists" was Dr. Arnold E. Erling, THE JOURNAL does not know. Official medical records fail to show, at least, that there is any other Erling in the state of Wisconsin.

W. W. FRITZ, M.D., Philadelphia.—Another of the "Censors." This presumably is W. Wallace Fritz, M.D., D.D.S., N.D., D.O., D.C., who was the "Dean" of the "American College of Neuropathy," and "Professor of Neuropathy" at the same institution. According to newspaper reports published when the "dean" of the American College of Neuropathy was called into court to testify regarding the "school," Fritz admitted that when he became dean of this "college," the "college" had three students and thirty "Faculty Members"! Fritz, it should be mentioned in passing, is a member of the Philadelphia County Medical Society and by virtue of this membership he is a Fellow of the American Medical Association! Recently Fritz's name appeared in connection with the formation of a new organization, founded, it appears, for the laudable purpose of fighting the "Medical Trust." Fritz, according to the newspaper reports, is treasurer of this new organization, which has adopted the inspiring title, "Constitutional Liberty League of America" and seems to be a later edition of the mushroom "National League for Medical Freedom." Quoting from the newspaper report:

"Dr. W. Wallace Fritz, a member of the American Medical Association, created a profound impression when he said that all health laws were written by agents of, or members of, the American Medical Association, and that this organization was at once the most powerful and the most harmful of all the American Trusts. Dr. Fritz then went on to say: 'Most of the drugs administered are worthless. Most of the doctors who prescribe them are incompetent, but both the injurious drug and the ignorant prescriber are protected, in and out of court, by the American Medical Association, which trust is now raising a vast fund with which to drive all druggists and healers out of the profession. Medicine is the camouflage used to conceal the most alert, the most rapacious and the least patriotic of all the trusts milking the American people. The tyranny of the Medical Trust is unbelievable. It is also un-American.'"

The Philadelphia *Sunday Transcript* of May 4, 1919, had a five column article under the name of W. Wallace Fritz. It is a most vituperative affair, and reeks with fire and brimstone. It is directed chiefly against the American Medical Association, and physicians are dubbed "Prescription Writing Drug Peddlers Who Prosper Through Monopolistic Laws Rather Than by the Practice of an Exact Science." In the course of this diatribe we read:

"The members of the American Medical Association are manifesting an unwarranted interest in the dear people, who, in their assumption, need quinn and mercurial guardian; who under this class legislation confines us to this monopoly of the big and little pill, is trying by hook and crook to shut out the natural and rational methods of cure which are driving the drug monopoly from the face of the earth. Diagnosis and consultation consist in four or five medical doctors, whose faces denote death, sitting around a sick man and guessing what ails him. After that has been performed they guess at what will cure him, and that is generally a sure sign the undertaker will follow."

C. O. LINDER, M.D., Spokane, Wash.—This gentleman (another "Censor"), seems to be an osteopath, who some years ago was "Assistant Secretary" of the "Washington's Physicians' Association," founded apparently by rebels within the osteopathic ranks who denounced the Washington Osteopathic Association as a "professional trust." Linder apparently claims graduation in 1905 from the "Thompsonian Medical College" of Allentown, Pa. The following item from the American Medical Directory regarding this school is of interest:

"Thompsonian Medical College, Allentown. Organized in 1904. Fraudulent. No evidence to show classes were ever held."

A. H. FLOWER, M.D., Boston.—Still another "Censor." Flower, according to the notice that appears in Polk's Directory for 1917, claims graduation in 1888 from the "American Health College" of Cincinnati, and in 1894 from the "American Health University" of Chicago. Quoting again from

the American Medical Directory, here is what we find regarding the former "college":

"*American Health College*, Cincinnati. Organized in 1874 and re-organized in 1876. Conducted by a Dr. Campbell who originated and copyrighted the so-called 'Vitapathic System.' Fraudulent. Extinct about 1888."

We have no record of an "American Health University" of Chicago, although there was an "Illinois Health University" of Chicago, one of the numerous diploma-mill swindles operated by Armstrong. It was declared fraudulent by the federal authorities and its charter was revoked in 1897. Flower, according to the notice in Polk's Directory, is:

Ex-President Maine Eclectic Society.
Ex-President New England Eclectic Medical Association.
Member National Eclectic Medical Association.
Member American Progressive Medical Society.
Member Massachusetts Eclectic Medical Society.

Z. L. BALDWIN, M.D., Kalamazoo, Mich.—Possibly the data just given concerning some of those whose names appeared on the organization's stationery are more than sufficient for the average physician to get a perspective of the Allied Medical Associations of America. Still, it is worth mentioning that in a letter recently sent out by Ignatz Mayer, extending an invitation to the annual convention of the Allied Medical Associations of America, Mayer took the opportunity of incorporating in his letter a letter which one of the members of the "association" had been sending out, urging individuals to join. The member in question was Dr. Z. L. Baldwin of Kalamazoo, Mich. Dr. Baldwin, as some of our readers may remember, is the gentleman who, a few years ago, was exploiting an "Intravenous Treatment" for the cure of tuberculosis. According to the claims made at that time:

"... for the first time in the history of medicine, we have a successful treatment for tuberculosis.

"... we are able to kill the germs of the disease in the body, thoroughly ridding it of all tubercular infection, destroying the germ and its poisons likewise."

This was a few years ago. Whether Dr. Baldwin is still specializing in consumption we do not know; apparently not, as we notice that at the first meeting of the Allied Medical Associations, Baldwin's name was on the program for the "Cure of Goiter by Adjustment of Lenses."

GEORGE STARR WHITE, M.D., F.S.Sc., LOND., Los Angeles, Calif.—A letter received by a physician a few days before the recent convention of the Allied Medical Associations, held out as an inducement to be present the fact that "Geo. S. White will show you how to diagnose disease by means of dif. colored lights and the reaction of the body to the magnetic meridian." Dr. George Starr White was the "Second Vice-President" of the Allied Medical Associations in 1918. White, according to our records, was graduated in 1908 when he was forty-two years old, by the New York Homeopathic Medical College and Hospital. He was licensed in New York in 1908, in California, Connecticut and Nevada in 1913, and in Michigan in 1916. He seems to have been one of the proponents of "spondylotherapy," "zonotherapy," etc., and in 1915 it was announced that he would give one week courses in "Spondylotherapy" in Chicago, Kansas City and Denver, respectively. In his advertisement he emphasized that he was a Fellow of the American Medical Association, which, while true at the time, is no longer true, as on Feb. 4, 1916, he was expelled from membership in the Los Angeles County Medical Association. In May, 1915, White was arrested in Chicago and fined \$100 and costs for practicing medicine without a license. Dr. White's specialty seems to be what is ponderously known as "Bio-Dynamo-Chromatic Diagnosis." This has been described by one of its enthusiastic adherents as "Diagnosis by Sympathetic Vagal-Reflex." To obtain the "Sympathetic Vagal-Reflex" it seems the patient must face east or west and have his bare abdomen percussed until a dull area is located. The patient is then faced north or south and again percussed. Then, it seems, different colored lights are thrown on the patient, the location of the

areas of dullness being determined meanwhile. A combination of ruby and blue light "will cause a reflex in cases of gonorrhea," a "green light will cause a reflex in cases of liver or gallbladder trouble," while the color for carcinoma is orange red! During the height of the influenza epidemic last winter, White seems to have put on the market "Valens Essential Oil Tablets" which were for "Gripping the Flu out of Influenza," and were also said greatly to benefit or cure incipient tuberculosis, hay fever, asthma, and "catar." The letters "F.S.Sc., Lond." after Dr. White's name look well, sound well, and have an air of erudition and mystery that is well worth what they cost. They mean "Fellow of the Incorporated Society of Science, Letters and Arts of London, Ltd." The "Fellowship" costs one guinea. Not a few "patent medicine" exploiters in the United States carry these mystic letters after their names. The society in question was a seriocomic concern that was exposed by London *Truth* some years ago and was also dealt with in THE JOURNAL of May 29, 1909, in connection with the "Aescol Consumption Cure" exposé.

So much for the Allied Medical Associations of America. At their recent meeting in New York City they got much newspaper publicity because of their action on the prohibition question. According to the newspaper reports, the organization adopted a resolution declaring that "properly brewed lager beer is absolutely essential in the treatment of certain cases." They were further reported as endorsing the manufacture of light wines and of beer containing not to exceed 2½ per cent. alcohol. As a piece of publicity work this resolution was all that its sponsors could expect. THE JOURNAL office was flooded with telegrams and letters from physicians, temperance workers, congressmen, church organizations, and others, asking, in effect, What is the Allied Medical Associations of America? This is our apology for giving the amount of space necessary to a proper understanding of this organization. Today the rocket of the Allied Medical Associations of America is blazing a more or less erratic course across the sky of publicity. The stick will be broken anon! Any resolution or expression of opinion by this organization, or others of its type, when dealing with the broader problems of public health, is wholly without scientific significance, whether such resolutions are good, bad or indifferent.

Correspondence

THE NYSTAGMUS TEST AND PRACTICE

To the Editor:—My attention has been called to an article by Fisher and Babcock on "The Reliability of the Nystagmus Test" (THE JOURNAL, March 15, 1919, p. 779) in which very definite misinformation is included. Since statements therein made seem to be borne out by the "official" account of the psychologic work published in the Manual of the Medical Research Laboratory, it is necessary to refer to that also in correcting the errors disseminated.

The account of the psychologic department included in the Manual was written by me, but was so "edited" after leaving my hands that misrepresentations may easily be based on it. The "editing" included not only the addition of an "editorial insert," and footnotes not labeled as inserts, but also the omission of important details concerning the experiments on nystagmus; and these omissions make possible inimical criticisms which would be contradicted by the omitted material. Since the Manual as separately printed contains a preface by Colonel Wilmer (this preface omitted from the Manual as printed in the larger book entitled Air Service Medical), it is only fair to state that the "editing" was not done by him, nor with his knowledge, but apparently after he had embarked for France. To those who know Colonel Wilmer this explanation is of course superfluous.

The work on nystagmus done by the Psychological Section of the Medical Research Laboratory was planned by me and authorized by the Medical Research Board and by the officer

in charge of the Medical Research Laboratory. For suggestions on the work reported in the Manual I am indebted to Mr. Arboz, a New York dancing teacher of much experience. The work was brilliantly carried out by Captain Bentley, professor of psychology in the University of Illinois, in conjunction with Captain (later Major) Wales, an otologist of enviable reputation. Since Professor Bentley had years of experience in psychophysics observations, and Dr. Wales had served for a considerable time on examining units, administering the official nystagmus test, the omission of the fact that they conducted the experiments, with the substitution of the statement that "these experiments were conducted by assistants in the laboratory" (Air Service Medical, p. 320), is significant in connection with the statement of Fisher and Babcock that "these experiments were conducted by observers not experienced in this type of examination" (THE JOURNAL, pp. 781-782).

Since the experiments were based on the "official" test as given under the examining boards, and not on tests which might have been substituted for this, the routine actually adopted by the physical examining units was followed (Air Service Medical, pp. 63, 64 and 75, 76, also plate facing p. 76) in observing nystagmus. This method does not involve *convex lenses* or the douching of subjects distinctly "normal" on the rotation test. The only additions were (1) an improved method of controlling the rate of rotation by using a metronome instead of a wrist watch, and (2) an improved method of recording the nystagmus duration, avoiding the common errors in stop-watch measurements. The importance of the first improvement was shown by our timing supposed "experts" in turning the chair: their times for ten rotations, officially twenty seconds, varying from as low as thirteen to as high as twenty-seven seconds, in tests from which published inferences were made.

The statement of Fisher and Babcock that "no medical examination had been made to determine whether or not the subjects of these experiments were normal" agrees with the footnote editorially added to the Manual that "of the six individuals used by the psychologic [sic] department for these experiments not one was examined physically beforehand; two of these six were discovered subsequently to be pathologic, the other four had meantime been lost sight of. This failure to establish positively the normality of the individual subjects before proceeding with the series of tests is most unfortunate as it makes it impossible to draw any scientific conclusions from the data obtained" (Air Service Medical, p. 322).

Since the subjects passed successfully the official nystagmus test, administered by Dr. Wales, with nystagmus close to the otologically optimal 26 seconds, the assumption that they were "pathologic" is a reflection on the official test as serious as any we might have made. Furthermore, aside from the question as to what might be the respects in which the two subjects were "subsequently" found to be "pathologic," in addition to the shortened nystagmus duration; it should be said that of the four who were "lost sight of," three at least were for months thereafter in the service in the Mineola laboratory or at branch laboratories at which there were competent medical men who could have made physical examinations at any time the otologists of the Air Service Medical might have requested it.

Even as edited in the official report, the results of the experiments are perfectly plain. Men who had passed the official nystagmus test with unexceptionable records *before* the practice series were unable to pass the test *after* the practice series, because of shortened nystagmus duration. Three interpretations are possible: (1) Pathologic men can easily pass the test. (2) Normal men may be turned down by the test. (3) Continued practice in rotation makes men less susceptible to the harmful effects of rotation. The Air Medical otologists seem, curiously enough, to have adopted the first interpretation. The third interpretation is, however, borne out by subsequent work, and by data now available from the flying fields, and from the study of dancers.

The Air Medical Service, I am informed, has been reorganized under the control of a new group of men. It is to be

hoped that they will openly correct the errors that have vitiated past publications and thus entitle future publications to credence, without waiting for the full freedom of presentation which will come at the termination of the war.

KNIGHT DUNLAP,

Professor of Experimental Psychology,
Johns Hopkins University.

"COMFORT AND COLD"

To the Editor:—The discussion of outdoor treatment in THE JOURNAL (June 21, 1919, p. 1859) seems to be confined to adapting the treatment to the comfort of the patient. My experience has been that the adaptation of the patient to the treatment is the essential thing, and unless this can be done, piling on more clothes is simply a limitation or defeat of the benefits of outdoor life. The mere breathing of fresh air constitutes only an infinitesimal part of the treatment. The patient needs the ventilation and stimulation of the air—of the cold air—and the adaptation of his body to the influence of cold air can never be accomplished by clothes. The latter may protect him, but it defeats the very purpose of outdoor life. It was not particularly the spruce boughs or the logs or even the blanket, although a certain amount of clothes is necessary, that kept the Canadian guide warm and ruddy but the reaction of his capillaries, from years of adaptation to the outdoors. I have slept snug and warm under a tarpaulin at minus 30 degrees and have had patients comfortable all winter in tents without heat when the thermometer went below minus 30, because accustomed to the cold. By moving patients into tents in autumn, or in emergencies by gradually graded cold baths, friction and brief exposure, a patient soon becomes accustomed to the change and resists extreme cold. People who live outdoors require less clothing than those who are housed. The problem of the invalid is to be able to get rid of the enervating influence of clothes; and instead of adapting the outdoors to the patient we should follow the axiom of adaptation to environment as the means toward survival.

J. HECTOR MacKAY, M.D., Houston, Texas.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

PARTOLA

To the Editor:—Will you kindly inform me what Partola is? It was brought to my attention by patients who buy it as a blood purifier, and when taken daily for some time, deleterious effects develop. One such patient is now in a "run down" condition with discoloration of the skin and a craving for the drug. Another patient took three tablets before going to bed, developed cramps and aborted the next day in her third month of pregnancy.

MYER M. MARBEL, M.D., Chicago.

ANSWER:—"Partola" was analyzed by the chemists of the Connecticut Agricultural Experiment Station and their report for 1915, Part 5, says of this product: "The tablets contain 2.64 grains phenolphthalein per tablet, 10.39 grains sugars and 1.86 grains starch, tale, color and oil of peppermint."

Education Versus Force.—In the enforcement of health regulations or sanitary laws, two methods present themselves: one that of education and persuasion; the other that of force, or the resort to prosecution under the terms of the law. The choice of which of the two will be most effective, and at the same time accomplish the most permanent results will, as a rule, depend on whether or not special or personal interests are involved. If there are no special financial interests involved and only the welfare of the community or public as a whole is to be taken into consideration, then the educational method is at once the most effective and most permanent in results.—Kansas State Board of Health.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ALABAMA: Montgomery, July 8. Chairman, Dr. S. W. Welch, State Capitol, Montgomery.
 CONNECTICUT: New Haven, July 8-9. Sec., Regular Bd., Dr. Charles A. Tuttle, 196 York St., New Haven; Sec., Homeopathic Bd., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven; Sec., Eclectic Bd., Dr. James E. Hart, 730 State St., Bridgeport.
 DISTRICT OF COLUMBIA: Washington, July 8-10. Sec., Dr. E. P. Copeland, The Rockingham, Washington.
 MASSACHUSETTS: Boston, July 8-10. Sec., Dr. Walter P. Bowers, State House, Boston.
 NEW MEXICO: Santa Fe, July 14. Sec., Dr. R. E. McBride, Los Crises.
 OKLAHOMA: Oklahoma City, July 8-9. Sec., Dr. J. J. Williams, Weatherford.
 PENNSYLVANIA: Philadelphia and Pittsburgh, July 8-10. Sec., Nathan C. Schaeffer, State Capitol, Harrisburg.
 RHODE ISLAND: Providence, July 10-11. Sec., Dr. B. U. Richards, State House, Providence.
 SOUTH DAKOTA: Deadwood, July 8. Sec., Dr. P. B. Jenkins, Washby.
 UTAH: Salt Lake City, July 7-8. Sec., Dr. G. F. Harding, 407 Templeton Bldg., Salt Lake City.
 WEST VIRGINIA: Huntington, July 8-10. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

Massachusetts February Examination

Dr. Walter P. Bowers, Secretary of Massachusetts Board of Registration in Medicine, reports the oral, written and practical examination held at Boston, Feb. 18-19, 1919. The examination covered 13 subjects and included 70 questions. An average of 75 per cent. was required to pass. Of the 70 candidates examined, 69 passed, including one osteopath, and one failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Boston University (1919)	76.2, 76.4, 78.3, 79.2, 79.5, 81.7, 77.7, 77.7, 78, 78.2, 78.2, 78.9, 79, 79, 79.2, 79.2, 79.4, 79.5, 79.9, 80, 80.5, 80.6, 80.7, 81, 81.3, 81.4, 82, 82, 82.2, 82.3, 82.3, 82.4, 82.5, 82.5, 82.5, 82.6, 82.7, 82.8, 82.8, 83, 83, 83, 83.3, 83.5, 83.7, 84, 84.2, 84.2, 85.4, 85.5, 85.5, 86.5.		
New York Homeo. Med. Coll. and Hospital	(1896)		75
University of Vermont	(1910)		75.8
FAILED			
Boston University	(1919)		69.3

Maine March Examination

Dr. Frank W. Searle, Secretary of the Maine Board of Registration in Medicine, reports the written examination held at Portland, March 11-12, 1919. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Four candidates were examined, all of whom passed. Two candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Boston University School of Medicine	(1918)		83
Harvard University	(1918)		85
Tufts College Medical School	(1898), 79; (1919)		86
LICENSED THROUGH RECIPROCITY			
College	Year Grad.	Reciprocity with	
Medical School of Maine	(1892)	New Hamp.	
University of Minnesota	(1899)	Minnesota	

Rice in the Chinese Diet.—Consul Julian Arnold at Peking says (*Commerce Reports*, Jan. 13, 1919) there is a mistaken idea abroad that every Chinese man, woman and child in China eats rice every day. As a matter of fact, there are millions of Chinese living in Shensi, Shansi, and North-western China, where rice is not grown, who never have seen or tasted rice. There are millions in the rice producing sections who cannot afford to eat rice regularly. With these qualifications it may perhaps be said that rice is the staple article of diet of the Chinese people, or, more correctly, of the people of Central and South China; though, strictly speaking, there is reason to believe that the sweet potato occupies an even more general place in the dietary of the people throughout all sections of China than does rice.

Book Notices

ADVANCED SUGGESTION (NEUROINDUCTION). By Haydn Brown, L.R.C.P. Cloth. Price, \$2.50. Pp. 342. New York: William Wood & Co., 1919.

In the preface the author naively states, concerning his book, "Nor can it be considered perfect." On page 11 he says: "Strange to say, . . . I never went through an elementary schooling." The reader will at once concede that both statements are unimpeachable. But it should be added that by the second bit of information apparently he means that he went through no developmental period of training in psychotherapeutics. No budding process for him. Lo! the perfect bloom instantly was there.

As nearly as can be gathered from widely scattered and obscure statements in the book, what the author means by "advanced suggestion" is a combination of persuasion, simple suggestion, and the laying on of hands. He calls it neuro-induction—whatever that may mean. Mayhap the following will clarify it for the reader:

"Neuroinduction involves limitation of both the physical and the mental energy of the patient down to a plain static receptivity on the part of the patient, and to an easy capability of comprehension of the remarks or sensations that are conveyed by the physician. It should, therefore, elicit no reply if consistently carried out, for this would entail effort at a time when absolute mental and physical relaxation was [sic] of prime necessity."

Or this:

"Suggestion should be considered as applicable, not only to brain conception, but to body perception. Under the methods which I employ a patient is not only instructed by words spoken, but his general system is at the same time induced by manipulations which are designed to impress, both wholly and locally."

The principal interest of the book lies in the opportunity it gives the reader to follow the mental wanderings of the author; for the mind of a practicing, licensed physician who makes a diagnosis of "general nervous chaos," cures prolapse of the rectum in a child of 2½ years by three sittings of neuroinduction, and advises the same esoteric procedure in hemorrhoids, varicose veins, valvular heart disease and warts, cannot be devoid of interest for even the casual thinker. The sole value of the book lies in its repetition of the lesson that medical men are so slow to learn. Times without number it has been shown that the ignorant enthusiast, the narrow minded faddist, the confident charlatan and the purblind mystic may get results where apparently a physician has failed. The latter's attention was riveted on organs and diseases to the exclusion of the man himself.

SURGICAL ASPECTS OF TYPHOID AND PARATYPHOID FEVERS. Founded on the Hunterian Lecture for 1917, Amplified and Revised by E. Welsh-Johnson, D.S.O., M.B., Ch.B., Temporary Colonel, Army Medical Service, British Expeditionary Force, France. With Foreword by Lieutenant-General T. H. Goodwin, C.B., C.M.G., D.S.O., Director-General, Army Medical Service. Price, \$4.50. Pp. 190, with 26 illustrations. New York: Oxford University Press, 1919.

This book is a well planned review of the surgical complications that developed under war conditions in 2,500 cases of typhoid and paratyphoid A and B. For many readers the chief point of interest of the book will lie in the emphasis which the author puts on the fact that there were so few surgical complications in the vaccinated as compared with the unvaccinated. In comparison with typhoid, paratyphoid A and B are found to be relatively mild diseases, although at times they, too, exhibit all of the complications of typhoid. Paratyphoid A is also a much milder disease than paratyphoid B.

A brief historical sketch of typhoid and paratyphoid is given, from which it appears that the evidence of the disease in war dates from 1643. Since its first appearance it has continued to be a menace to the armies of all countries. In 1896 the paratyphoid bacillus was first isolated and designated as distinct from the typhoid bacillus. It was not, however, classified until 1912.

In the large British isolation hospital in France, where these 2,500 cases were recorded, a careful segregation of all cases into typhoid and paratyphoid A and B was made and the bacteriologic findings were kept separate, which thus permitted an interesting and instructive comparison of these three so closely allied diseases. The value of vaccination was demonstrated by the lower incidence of typhoid and the lower mortality among the vaccinated. The bacteria found in the complications depend on the time of onset. If complications occur late in the disease or in convalescence, the specific organisms are usually found in pure culture; but in early complications, pyogenic organisms are usually found. Perforation is of primary surgical importance, as an early diagnosis must be made. Paratyphoid was found to involve the large intestine more than typhoid. The author recommends a midline incision in order thoroughly to explore the abdomen. He uses local anesthesia or a combination of it with gas and oxygen or small doses of ether inhalation. Other abdominal conditions, such as abscess of the liver or spleen, or primary peritonitis, occasionally occur. When the biliary passages become involved, the author advises conservative measures if possible. The genito-urinary system was most often involved in the paratyphoid B infection. Tracheotomy was at times necessary for laryngitis. Chest complications were also most common in paratyphoid B infection. The author found that in cases with symptoms of spondylitis there frequently were organic lesions. Ear complications were common, and brain abscesses are said to develop at times without ear involvement.

The carrier problem is unsettled and the author thinks that, while the gallbladder may be the source of the infection, it may be the spleen, the bone marrow or other foci.

Social Medicine, Medical Economics and Miscellany

The New Science of Industrial Physiology

By the term "Industrial Physiology" Frederick S. Lee (*Public Health Reports* 34:723 [April 11] 1919), professor of physiology in Columbia University, means the sum of knowledge pertaining to the working of the human mechanism in industrial activity. It thus includes psychologic phenomena as well as those more technically recognized as physiologic.

It has come to be recognized that industrial success is dependent in large measure on the efficiency of the labor element. In the body of the worker, with its combination of living organs and tissues, undergoing chemical reactions and transforming energy under the direction of a nervous system, we have a very intricate mechanism, on the proper working of which depend in large degree industrial efficiency and, through it, industrial success. The war, with its extraordinary call on human energies in the field of industry, has emphasized as never before the hygienic, or more properly speaking, the physiologic, aspects of industrial activity, and during the past four years the beginnings of a new science, an industrial physiology, have appeared and attracted the attention of scientific men and the more sagacious of industrial leaders. Some of the results of investigations already made are:

Certain physiologic and psychologic tests have been employed with workers, and it appears practicable to employ some of these tests in selecting workers and assigning them to their jobs.

The output of the successive hours of the working day in different types of operations has been measured, and the daily curves of the output have been plotted. These vary with the kind of operation, but are alike in showing a reduced efficiency, indicating a growing fatigue, as the day proceeds.

Reduction in the length of the working day is characterized by an increase in the output of the successive hours, and usually by a total increase in that of the day. The optimum duration of work probably varies with the character of the work itself.

The introduction of resting periods in the working spell is accompanied, especially where the working day is long, by a total increase in the day's production. A five-hour working spell, unbroken by resting periods, is probably always too long.

Overtime following a day of labor is undesirable, as is also Saturday work following a week's labor. These tend to impair the working power of the worker.

A hot day tends to impair strength and reduce output. Every effort should be made to keep the body of the worker cool.

Night work is, in general, less efficient than day work. Its total output is less, and this, with a long working night, falls off enormously in the early morning hours. Alternation of periods of night work with periods of day work is more profitable than continuous night work.

Women are capable of performing a much greater variety of industrial operations than has heretofore been recognized. They should not be employed for night work. Statistics show that they are absent from their work more frequently than men. The problem of women as compared with men in industry is not that of their greater or less general efficiency, but rather a problem of what types of work each sex is best fitted for.

Accidents to workers are a grave source of inefficiency. They are caused by fatigue, inexperience, speed of working, insufficient lighting, high temperature and other factors. Many industrial accidents are preventable, and adequate provisions for industrial measures tend to diminish the seriousness of accidents.

Food and efficiency are directly connected with one another, and suitable and adequate food can probably be best provided through the establishment of industrial canteens.

A high labor turnover is incompatible with the highest degree of efficiency. It is expensive, in that it imposes on the employer the necessity of training new workers, and it is a serious factor in the causation of accidents.

Physiologic analysis of certain operations have been made, by means of the cinematograph and other methods, and it has been found possible to eliminate unnecessary motions and to train workers so as to secure a more regular rhythm, such measures increasing efficiency.

The self-limitation of work on the part of workers has been studied and found to be very common. Every legitimate effort should be employed by foremen and managers to eliminate this and to induce workers to work up to their physiologic capacity. Driving workers beyond their physiologic capacity defeats its own ends.

These and similar topics have been the subject of investigation, in England by the Health of Munition Workers Committee, and later by the Industrial Fatigue Research Board, which has been appointed jointly by the Department of Scientific and Industrial Research and the Medical Research Committee. The chairman of this board is Professor Sherrington, F.R.S., Oxford, and its membership comprises many well-known men.

In America during the past eighteen months the Public Health Service, with the cooperation of the committees on fatigue in industrial pursuits and on industrial fatigue, of the National Research Council and the Council of National Defense, respectively, has been conducting a fruitful investigation of a variety of topics within the scope of industrial physiology, and its report will soon be ready for publication.

Work in this line is also engaging the attention of the universities in the three countries that are of leading industrial importance, notably in the case of Prof. Stanley Kent, the newly appointed director of the Department of Industrial Administration in the Municipal Technical College of Victoria University, Manchester. In our own country the work has been undertaken by Harvard University, and similar activities are expected from the School of Hygiene and Public Health recently established in Johns Hopkins University.

"With the ending of the war," says Dr. Lee, "the problems of industry press for solution more earnestly than ever, and one of the most timely of these problems concerns the physiologic aspects of the work of the human machine. On us in America, where industry is destined to lead the world, there is imposed a grave duty—that of directing investigation along such lines that empiricism and tradition, those two obstacles to progress which have long been potent in industrial evolution, shall be cast out and industry shall be placed permanently on a scientific basis."

Mortality After Operation for Gastric and Duodenal Ulcers

At the request of the Association of Life Insurance Medical Directors, Dr. Angin B. Hobbs made an investigation as to the mortality following operations for gastric and duodenal ulcers. Patients, operated on at the Mayo Clinic from Jan. 1, 1910, to December, 1915, were made the subjects of this investigation. When a record of the subsequent outcome of the case was not obtainable from the clinic, the insurance companies came to the rescue, so that in 96 per cent. of the cases the history after operation was known. On

545 persons operated on for gastric ulcer, twenty-four died as the result of the operation, an operative mortality of 4.5 per cent. Among the 1,684 operations for duodenal ulcer, there were thirty-three operative mortalities, or 2 per cent. The operative death rate from gastric ulcer, including deaths in the hospital soon after operation, was therefore fully twice that from duodenal ulcer. The 521 persons operated on for gastric ulcer were under observation for an average of 3.6 years, and during that time, eighty-eight, or 17 per cent., died. The 1,651 duodenal ulcer patients were under observation on an average of 3.4 years, and during that time, eighty-five, or about 5 per cent., died. Ninety-one persons who had both gastric and duodenal ulcer were under observation on an average of 3.8 years. Nine of this number, or 10 per cent., died. Therefore, the mortality among persons operated on for gastric ulcers is three times as high as among those operated on for duodenal ulcer during the three years following the operation. The mortality among the former decreases relatively after operation. This investigation is said to be the first of the kind made.

Medicolegal

Release to Company No Defense to Surgeon Forgetting Identity of Patient

(*Purchase v. Seelye (Mass.)*, 121 N. E. R. 413)

The Supreme Judicial Court of Massachusetts, in this action brought to recover for an unauthorized surgical operation performed by the defendant on the plaintiff, wherein there was a verdict for the defendant, sustains exceptions to the admission in evidence of a release to a railroad company, and to a ruling that the release was a bar to this action. The court says that the plaintiff, while in the employ of the railroad company, suffered a rupture in his right groin. He consulted the defendant, who operated on him the next day. The day following he discovered that the operation had been performed on his left side, and spoke about it to the defendant, who, he testified, said that he mistook him for another patient that had a hernia on the left side. Afterward an operation was performed by the defendant on the plaintiff's right side. Later the plaintiff made a settlement of his claim against the railroad company, and executed and delivered to it a release of all claims and demands "arising or which may arise out of said injury." This action against the surgeon was brought after that settlement, and an important question was whether it was barred by the release.

If the plaintiff's employer, in an action brought against it to recover for original injury, would have been liable for the negligence of the defendant in improperly treating the plaintiff, then the release included such damages, and was a bar to the present action for the reason that in such a case the plaintiff had a claim against both the railroad company and the surgeon for the same cause of action, and a release of one of the alleged wrongdoers would operate as a release of both. It is well settled in Massachusetts, and in many other jurisdictions, that in an action for personal injuries arising out of the alleged negligence of the defendant, the plaintiff is entitled to recover for the injuries resulting from the defendant's negligence although such injuries are aggravated by the negligence of an attending physician if, in his selection and employment, the plaintiff was in the exercise of reasonable care. The question was whether the act of the defendant in operating by mistake on the plaintiff's left side was a natural and probable result of the negligence of the railroad company. The court is of the opinion that the general rule as stated above was not applicable to the case at bar. There was sufficient evidence to show that the defendant made a mistake in the identity of the plaintiff at the time the operation was performed; that he then believed he was operating on another patient who had a hernia on his left side. The railroad company could not be held liable because of his mistaken belief that he was operating on some person other than the plaintiff; such a mistake was not an act of negligence which could be found to flow legitimately

as a natural consequence of the original injury. The fact that the mistake might possibly occur was not enough to charge the railroad company with liability; the unskillful or improper treatment must have been legally and constructively anticipated by the original wrongdoer as a rational and probable result of the first injury. The court is of the opinion that the act of the defendant in operating on the wrong side was a wholly wrongful, independent and intervening cause for which the original wrongdoer was in no way responsible.

If it be assumed that the release was valid and a bar to any claim which the plaintiff had against the railroad company, still a majority of the court is of the opinion, for reasons stated, that it was not a defense to the present action, and was not admissible in evidence. It was unnecessary to decide whether the railroad company would have been liable for the aggravation of the plaintiff's injury by the mistake of the defendant in operating on the wrong side, had there been no mistake with reference to the identity of the patient.

Right to Select Physician or Hospital Under Workmen's Compensation Act

(*Leadbetter et al. v. Industrial Accident Commission (Calif.)*, 177 Pac. R. 449; *Cella v. Industrial Accident Commission et al. (Calif.)*, 177 Pac. R. 490)

The Supreme Court of California says, in the Leadbetter case, that the workmen's compensation act of that state (Section 15a) imposes on the employer the duty to provide medical, surgical and hospital treatment, and, "in case of his neglect or refusal seasonably to do so," makes him liable for the reasonable expense incurred by the employee in providing the treatment. The intent of the act obviously is that the employer shall, in the first instance, have the right to designate and select the physicians who are to give treatment to the employee. The latter is authorized to make his own selection at the expense of the employer only when the employer has neglected or refused to provide the necessary service.

The District Court of Appeal of California, First District, Division 1, in affirming, in the Cella case, an order of the commission refusing to make an award in his behalf covering hospital charges, says that he was injured while in the employ of a company, and was told by the company's physician to go to the St. Francis Hospital. He did not do so, but went to St. Joseph's Hospital. He claimed that he did this through ignorance, being an Italian who could neither read, write nor speak English. However, the fact was clearly established that he was directed to go to the St. Francis Hospital and the address was given in writing. These facts did not show any neglect or refusal on the part of the company to furnish him hospital service. Yet it is clear that the commission could not make an award to him for such services except it be first shown that the company had neglected or refused to furnish such service. The commission did not exceed its jurisdiction in refusing him an award.

Responsibility for Erroneous Diagnosis

(*McCollum v. Barr (Calif.)*, 176 Pac. R. 463)

The District Court of Appeals of California, Third District, affirms a judgment for \$1,000 damages in favor of the plaintiff for alleged unskillful treatment of his right forearm, which was fractured in cranking an automobile. The court says that the defendant not only diagnosed the case as one of dislocation and treated it as such for seven weeks, but, in his verified answer to the complaint, he denied that the plaintiff's forearm suffered a fracture, although the testimony of two other physicians left no doubt that both bones of the forearm were broken. It was very clear that the defendant made a faulty and erroneous diagnosis of the plaintiff's injury and adhered to it during the period of his treatment. Did the evidence sufficiently support the implied finding of the jury that this erroneous diagnosis was illy considered and carelessly or negligently made and not warranted by the facts as they presented themselves to the defendant? In solving the question the court must give to

the evidence such interpretation as the jury gave it, and deduce from it such inferences as the jury deduced, if such interpretation and deduction were such as reasonable men might make in the discharge of their duties as jurymen.

The expert witnesses seemed to agree that in case of doubt the roentgen ray, if accessible, should be used. There was testimony of the experts that where discoloration existed to the extent shown in this case, though not conclusive, it was indicative of fracture. The defendant testified that he had no doubt of the correctness of his diagnosis. But was he justified, in view of the facts, in closing his mind against any doubt, and neglecting an available and accepted means of testing the correctness of his judgment? The defendant's ability and skill as a physician and surgeon seemed not to be questioned. The point urged was that in this particular instance he did not exercise the care and skill of which he was capable, and did not "use ordinary care, diligence, and skill, according to the circumstances of the case," as the jury were instructed was his duty. It might be conceded that the defendant's expert witnesses were correct in their opinion that ordinary skill did not require of the defendant that he should have used the roentgen ray in making his diagnosis. But there still remained the question whether the defendant did in fact exercise ordinary care and skill in making his diagnosis, and the still further question whether, had he exercised ordinary care and skill in his treatment, he would not have discovered the error in his diagnosis.

It may be doubted that the degree of skill and care of a physician in diagnosing and treating disease is the same as that of a surgeon in all cases of surgery. A broken or dislocated member of the body, usually discernible to the eye or the touch of the surgeon, presents an entirely different problem from internal disorders whose manifestations are obscure and often misleading. However this may be, the question is always open to inquiry whether or not the physician or surgeon in a given case did in fact exercise ordinary skill and care.

Loss of One Member Before Employment and One After

(*Wabash Railway Company v. Industrial Commission et al.* (Ill.), 121 N. E. R. 569)

The Supreme Court of Illinois affirms a judgment for compensation under the workmen's compensation act for a total and permanent disability in a case in which a man whose left arm had been amputated near the shoulder was employed by the railway company as a night watchman and while so employed fell over a pile of scrap iron and injured his left knee, as a result of which injury tuberculosis of the bone set in and his left leg was amputated about 6 inches below the hip joint. The company contended that the loss of one leg does not constitute total permanent disability; but the man contended that the loss of his left leg, combined with the previous loss of his left arm, constituted permanent disability. The court says that this precise question has not arisen before in Illinois. It has arisen in some other jurisdictions under compensation acts similar to that of Illinois. In Massachusetts and New York it has been held that under such circumstances the disability occasioned is total and permanent. This court is disposed to follow the reasoning of the Massachusetts court construing a statute quite similar to that of Illinois, and to hold that the latter applies when the loss of one of the members mentioned occurred previous to the employment, and the loss of the other occurred as the result of an injury arising out and in the course of the employment. This, in this court's opinion, is the fair intent and meaning of the act. When this man was employed by the railway company, he had lost his left arm, and his capacity for work was to that extent impaired. He was employed to do work which could be performed by a man having but one arm, and he was paid on that basis. By the loss of his leg such capacity as he had for work was entirely destroyed, and under the provisions of the statute he was entitled to compensation for total permanent disability. Nor does such construction work any hardship on the company, as the man was employed and paid as a man of limited capacity, and the compensation which the company is required to pay is based

on the wages it was paying him as a man of limited capacity. The fact that he may have been predisposed to tuberculosis of the bones did not affect the result, as the evidence showed that the tuberculosis of the left knee developed as a result of the injury.

When Employer Is Not Liable for Medical Services

(*Radil v. Morris & Co. (Nebr.)*, 170 N. W. R. 363)

The Supreme Court of Nebraska holds that, under Section 3601 of the Revised Statutes of Nebraska of 1913, as amended by the Laws of 1917, Chapter 85, Section 6, an employer, who offers to furnish without charge to an injured employee the reasonable services of a competent physician and medicines as and when needed, and within the value and for the time contemplated by the statute, cannot be held liable for such services by such employee, who has refused such offer by the employer and has obtained such services and medicines elsewhere. The court says that the plaintiff in this case sustained an accidental injury while in the employ of the defendant, and as a result of the accident a part of the second finger of his left hand was bruised and fractured, and afterward amputated at the joint. He recovered an award from the compensation commissioner on account of the injury, and for \$129 expenses incurred for medical and surgical treatment by a physician other than the one regularly furnished by the defendant. The plaintiff argued that, because an operation became necessary, he was therefore at liberty to make his own selection of a physician, and that the defendant became liable under the statute for the reasonable expenses so incurred. But the court is of the opinion that, the employer having been made liable for the services contemplated by the statute, it would seem from the language used that it must have been the legislative intent that he should be permitted to furnish a physician of his own choice, and if his selection is such as would satisfy a reasonable man under like circumstances, the employee would not then be heard to complain. That is the general rule in manufacturing centers, where employers' liability acts with provisions similar to those of the Nebraska act were in effect before the latter was adopted. It seems to the court that the plaintiff's conduct was in effect and within the meaning of the statute an unjustifiable refusal to allow the defendant to furnish the reasonable services and medicines that the act contemplates, and that the defendant was not therefore liable for the medical expenses that he incurred. Wherefore a judgment of the district court, which disallowed the bill for \$129 for medical services, is affirmed.

Bars Testimony as to What Roentgenograms Show

(*Lang v. Marshalltown Light, Power & Railway Co. (Iowa)*, 170 N. W. R. 463)

The Supreme Court of Iowa holds that there was no error in a ruling in this personal injury case sustaining objection to questions such as one asking a physician to state whether or not a certain roentgenogram did, or did not, show a curvature of the spine, as appeared in the negative. The court says that the defendant cited a number of cases to the proposition that roentgen-ray negatives and photographs, properly verified, are admissible in evidence, and this proposition was not disputed by the plaintiff. Cases were also cited by the defendant, holding that it is proper for experts to interpret and explain roentgen-ray plates to the jury. Among these was the case of *State v. Matheson*, 142 Iowa, 414, 130 N. W. 1036. It was claimed, too, that some of the cases hold that a witness may testify as to what the photograph shows. But the court thinks that the questions asked in this case, and the ruling thereon, were within the ruling of *Elzig v. Roles*, 135 Iowa, 208, 112 N. W. 540, wherein it was said, in effect, that, as demonstrative evidence, roentgenograms serve to explain or illustrate and apply the testimony, and are aids to the jury in comprehending the questions in dispute. When taken for either purpose they are the best evidence of what appears on them. The rule exacting the best evidence applies to the testimony of experts, as well as to that of other witnesses, and it was error to permit a physician to testify to what appeared in a roentgenogram.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

Climacteric Hypertension: Study of High Blood Pressure During and Following Menopause. A. H. Hopkins, Philadelphia.—p. 826.

Heart Muscle Equations.—No single procedure or formula gives universally applicable information regarding the integrity of the heart muscle in a given case. In the order of their value as indications of a damaged myocardium, Dana places the following criteria: The general appearance of the subject, with special reference to his color, to the occurrence of actual dyspnea, or distress, or cough or exhaustion resulting from exercise; the presence of a true gallop rhythm at rest or following exercise; the production, as the result of exercise, of a relative mitral insufficiency, as evidenced by a murmur; the presence, in the absence of valvular disease, of signs of decompensation, such as edema of the lungs or of the extremities, whether at rest or after exercise; weakening of the first sound at the apex, resulting from the effort test; increased strength of the first sound over the right ventricle as compared with the first sound at the apex, occurring after exertion; weakened first sound at the apex, at rest, in the absence of emphysema; the production, following the effort test, of irregular heart action or the increase in irregularity, already present, brought on by exertion; loss or weakening of the second sound at the apex, due to exercise; variations in the systolic, in the diastolic or in the pulse-pressure are believed to give relatively little information regarding the cardiac function.

Influenza in Children.—Only about 10 per cent. of the children whose cases were reviewed by LaFetra had pneumonia. About four-fifths of the cases with lung involvement took the form of bronchopneumonia. The most peculiar feature of bronchopneumonia cases was the occurrence in six instances of interstitial emphysema. Appearing first above or below the clavicles it extended to the thorax, the arm and the back, in two cases down as far as the nipple and in one instance down the trunk and as far as the middle of the thigh, the crepitations being felt throughout the entire area. Apparently the symptom occurs in only the severest cases, for five of the six patients died.

Case of Human Anthrax.—In the case cited by the Regans, the disease involved the neck. The anthrax bacillus was not only recovered locally from the lesion, but was also found in the patient's shaving brush. Anti-anthrax serum was employed exclusively in the treatment, given both by intramuscular injection and locally by injection into the tissues immediately surrounding the malignant pustule. The latter method of treatment proved exceedingly effective. Excision of the lesion proved entirely unnecessary after the local application of the serum.

Hematogenous Streptococcic Peritonitis.—Seven of Rabinowitz's eight cases occurred in females; their ages ranged from 10 months to 21 years. All occurred during the winter and spring months. This corresponds exactly to the seasonal incidence of the streptococcic throat epidemics. In but few instances was there a history of pain in the throat or tonsillitis. The history, as a rule, was that the patient had suddenly, while in the best of health, been taken sick with high fever, reaching 104 F., or over, severe generalized abdominal pain, repeated vomiting and marked prostration. These phenomena persisted until admission. When the peritonitis followed a distinct anginal attack a period of well-being, lasting three or four days, frequently intervened before the sudden development of the peritonic symptoms. The temperature remained high without marked oscillations. The pulse was invariably very rapid and out of proportion to the temperature. It was at first of a bounding character. Herpes labialis was invariably absent in this series. Diarrhea occurred in but few of the cases. The leukocyte count was very high, ranging between 25,000 and 64,000, on the average of 40,000. The polymorphonuclear count varied from 85 to 97 per cent., on the average 92 per cent. The abdomen was tender and moderately rigid all over. There was no marked distention, and careful examination only infrequently revealed evidences of fluid in the flanks. The patient rapidly passed into the terminal phase of peritonitis, with the usual attendant phenomena of Hippocratic facies, livid, clammy extremities and running, thready pulse. Death occurred in from three to eight days of the onset of the peritonic stage, and was the result of cardiac and vasomotor collapse, induced by a virulent toxemia.

Gastric Mucosa in Meckel's Diverticulum Producing Intestinal Obstruction.—In a case of partial obstruction caused by Meckel's diverticulum a striking variation was discovered at operation in the mucous membrane of the distal half of the diverticulum. This area of mucous membrane at the tip of Meckel's diverticulum was differentiated from the proximal mucosa by a sharp line of demarcation and by a difference in color, surface character and in thickness. On subsequent sectioning, this area of mucosa proved to be of the precise character of gastric (fundus) mucosa, containing the typical gastric glands (foveolae gastricae) composed of the two distinctive types of cells, the parietal and chief, each of which presented their characteristics of morphology and of staining reaction. The best explanation for the occurrence of these structures, in Goetsch's opinion, is that the original endodermal lining of the intestinal tube and ophalomesenteric duct possess potentialities of development into any of the glandular structures of the adult intestinal tract or of its accessory glands, and under the influence of certain circumstances, which are not understood, groups of cells may retain one or the other potentiality and develop into a glandular tissue very different from the surrounding glandular tissues and resembling the adult organ, such as stomach or pancreas, which may be far removed.

Phagocytosis and Agglutination of Serum in Acute Lobar Pneumonia.—Of thirty-three cases of acute lobar pneumonia in which the phagocytic activity of the serum after crisis or lysis was tested by Clough, with the homologous strain of pneumococcus, twenty-eight, or 85 per cent., gave definitely positive results. These results confirm and extend those previously reported by the author. In twenty-six, or 79 per cent., of these cases agglutinative activity was also demonstrable. In eighteen cases in which definite phagocytic activity was demonstrable in the serum after recovery either for the homologous strain or for a stock strain of known type, tests were also made with serum obtained during the acute stage of the disease, and negative results were obtained in fifteen. The three serums which showed phagocytic activity were obtained twenty-four hours or less before crisis. Serum was also examined from seven patients who subsequently died of the disease, and negative reactions were obtained in six instances. A positive reaction was obtained in one patient, who, after a short remission, died apparently of sepsis and endocarditis. This phagocytic and agglutinative activity of the serum developed after the recovery from infection with pneumococci of all the recognized types. It was strictly limited to organisms of the same type as that with which the patient was infected, but, as a rule, was exerted equally well on the homologous strain and on heterologous strains of the same type. It is, therefore, specific as to type, but not specific as to strain, as the author originally believed. The agglutinative activity of the serum as observed in these tests paralleled closely the phagocytic activity. In the case of atypical Type II and Type III strains it was not so sharply specific as was the phagocytic activity. This phagocytic activity is entirely different from a possible rise in opsonic index, in that it brings about active phagocytosis of a virulent pneumococcus, not at all phagocytizable in normal human serum. The active substances in the serum also differ from the opsonins of normal serum in that they are usually thermostable; they usually remain active for several weeks in serum preserved *in vitro*; and when their activity is lost, they cannot be reactivated by fresh normal serum (complement). They are, therefore, qualitatively comparable with the bacteriotropins of potent immune serum. In view of these facts, Clough concludes that this factor plays an important part in bringing about recovery in man.

*Spinal Anesthesia in Upper Abdominal Surgery. L. L. Stanley, San Quentin.—p. 183.

Smallpox Increasing in California.—Gillihan attempts to show that smallpox is increasing throughout the world, not only in number of cases, but also in death rates, and that California shares in this increase. He says that the mild form of smallpox and the severe reactions following poor methods of vaccination has become almost universal. Vaccination is the only protection against smallpox, but this protection lasts for only a few years, and must be repeated at intervals if an individual desires to avoid the smallpox. Methods of vaccination are recommended which do not produce harmful results. In Gillihan's opinion vaccination should be done by special officers delegated to that duty, it should be done by prescribed methods, and it should be free to all people.

Spinal Anesthesia in Upper Abdominal Surgery.—Stanley analyzes briefly 603 operations done under spinal anesthesia on inmates of the California State Prison. There have not been any bad results.

*Experiments on Mode of Infection in Epidemic Meningitis. H. L. Amoss and F. Elerson, New York.—p. 605.

Edema of Lungs as Cause of Death.—The importance of pulmonary edema per se as a cause of death is questioned by Winternitz and Lambert. They conclude that edema of the lungs in general is merely an indicator of some underlying disorder and is rarely, if ever, directly responsible for the death of the patient or animal.

Yellow Fever in Guayaquil.—The clinical and pathologic features of the yellow fever prevalent in Guayaquil conform with those described by other investigators of this disease as it has occurred elsewhere, both epidemically and endemically.

Transmission Experiments on Yellow Fever.—By injecting into guinea-pigs the blood of yellow fever cases occurring in Guayaquil a group of symptoms and lesions closely resembling those observed in human yellow fever were induced by Noguchi in a limited number of instances. Of seventy-four guinea-pigs inoculated with specimens of blood from twenty-seven cases of yellow fever, eight, representing six cases, came down with the symptoms. In the blood, liver, and kidneys of the guinea-pigs experimentally infected with the blood of yellow fever patients a minute organism was demonstrated which closely resembles in morphology the causative agent of infectious jaundice (*Leptospira icterohaemorrhagiae*). The leptospira transmitted from yellow fever cases to guinea-pigs was found to induce similar symptoms and lesions on further passage into normal guinea-pigs. The leptospira obtained from cases of yellow fever has been given the provisional name of *Leptospira icteroides*.

Findings in Animals Infected Experimentally with Yellow Fever.—Studies are reported by Noguchi on the type of disease induced in guinea-pigs, dogs and monkeys by inoculating them (1) with the blood or organ emulsions of guinea-pigs or other susceptible animals experimentally infected with *Leptospira icteroides* and (2) with a pure culture of the organism. The symptoms and lesions observed closely parallel those of human yellow fever. The pathologic changes occurring in human cases of yellow fever are similar to those induced by inoculation in guinea-pigs and mammals and in respect to their intensity stand intermediate between those arising in the two animals mentioned.

Mode of Infection in Epidemic Meningitis.—The experiments reported on by Amoss and Elbersen do not lend any support to the notion that an intraspinal injection of the antimeningococcus serum, early in the course of invasion of meningococcus in man, and possibly at a period at which the meninges do not yet show evidences of inflammation, favors its diversion from the blood stream into the sub-arachnoid space.

*Red Cell Globulin. C. B. Bennett and C. L. A. Schmidt, Berkeley, Calif.—p. 29.

Immunity by Tissue Culture Method.—Many attempts have been made to devise a simple and accurate laboratory method for determining the presence of toxic and antitoxic substances in the blood of persons suffering from acute infections of various kinds and in the blood of normal individuals. Chicken tissue can be readily cultivated in drops of human plasma. It seemed to Burrows and Suzuki, therefore, that one might use this tissue to develop a method for the detection of small quantities of diphtheria toxin and antitoxic substances in the blood of patients or normal individuals. As an introduction to this particular use of the method they have studied the neutralizing value of the blood of a number of normal adults and children. The blood of twenty-seven adults and eleven children has been studied by this method. In most instances the Schick reaction was also performed. It is evident that this method finds application, with slight variation in the choice of the tissue, not only for the study of diphtheria but for the study of other toxins and antitoxic substances.

Antibody Production by Injecting Pancreatic Ferments.—Wago claims that the precipitins and complement deviating antibodies produced in this manner are distinct from such antibodies as may inhibit the proteolytic ferments of pancreatin. The former, as in the present experiments, may be produced in large amounts in the absence of the production of the latter in any degree whatsoever. Following intravenous injection of pancreatin, the proteolytic ferments and protein of pancreatin are extensively excreted by the

urine. The antigenic value of pancreatin for stimulating the production of antibodies to the contained proteins is enhanced by an alcohol modification of the pancreatin. The production of precipitins to pancreatin as a soluble antigen is favorably influenced by the intravenous injection of sodium iodoxybenzoate. The production of precipitins to pancreatin may be enhanced to the greatest degree by employing alcohol modified pancreatin as antigen and by accompanying its injection with that of sodium iodoxybenzoate.

Red Cell Globulin.—It was found by Bennett and Schmidt that the serums of animals immunized with CO₂ globulin from washed red cells contained immune bodies specific for this globulin and not for the CO₂ globulin from the homologous serums and substances which in the presence of alexin will cause lysis of the homologous red cells and in the absence of alexin cause agglutination of these cells. It is not definitely stated whether the CO₂ globulin from red cells is the antigen concerned in the production of a lysin for the homologous red cell or a substance intimately associated with it. The possibilities are discussed.

Chip Fractures of Phalanges.—Hurley reports seven cases in which a small fragment of bone was broken off from the terminal phalanx of a finger by an industrial accident. He urges that all contusions of fingers and toes, especially those accompanied by any degree of swelling, should be examined with the roentgen ray. The general plan of treatment should be expectant at first. In the face of increasing swelling or tenderness after the first few days, or persistent tenderness after the fourth week, the removal of the chip should be accomplished. The sooner the chip is removed after the fourth week, the better the chance of having the wound heal by first intention.

Serotherapy in Lobar Pneumonia.—One hundred and twenty-one cases of primary lobar pneumonia were analyzed by Hart. In every case at least one blood culture was taken; in a number of cases as many as eight or nine cultures were studied. A positive blood culture was obtained in forty cases. The sputum was studied in every case in which a suitable specimen could be secured. Pneumococcus type I was found in thirty-three cases; type II in thirty cases; type III in ten cases and type IV in twenty-three cases. In twenty-five cases miscellaneous organisms were found. Forty-one patients died. Serum was administered in thirty-one cases of type I according to the rules laid down by the Rockefeller investigators. While the evidence presented is fragmentary it seems to indicate that the administration of serum affords a definite aid to nature's effort to sterilize the blood stream. The failures which are recorded are very instructive. In each case there was a localized focus of infection which continued to furnish pneumococci to the blood stream. In one instance this was an empyema; in three others an acute endocarditis was present, and in two of these, which were examined postmortem, there were found on the heart valves fresh vegetations containing pneumococci. Hart emphasizes that a positive blood culture in

lobar pneumonia is usually an indication that one may expect a severe course. It is rare for a patient who has received serum to escape a subsequent "serum illness." This may be mild or severe, but bears no relationship to the amount of serum given. Serum illness in these cases does not endanger life.

Etiology of Thrombo-Angiitis Obliterans.—Further study and observation of patients suffering from so-called thrombo-angiitis obliterans have led Meyer to the conviction that this trouble is a systemic disease and not, as Buerger believes, a primary affection of the blood vessels. In his opinion there seems to be just one etiologic factor responsible for the characteristic syndrome, and that is tobacco smoke poisoning.

Nonspecific Proteins in Influenzal Pneumonia.—Two cases are reported by Squier in which homologous citrated blood was transfused. Transfusion produced a severe reaction followed by a drop in temperature by crisis and by prompt recovery. Two transfusions with immune blood which caused no reaction were followed by no change in the temperature, pulse, respiration or general physical condition. When typhoid substance was used (in two cases) and a typical protein reaction obtained there was in each instance a sharp fall in temperature and a dramatic improvement in the patient. These results have led Squier to believe that nonspecific protein therapy has a very definite and important place in the treatment of influenzal pneumonia.

Experimental Production of Pancreatitis.—Archibald, records experiments performed with the view to induce pancreatitis with bile, by forcing this bile into the pancreas. The experiments were successful. An acute hemorrhagic pancreatitis was produced, with death in half an hour. Archibald used ox bile infected with various organisms, human bile from a cholecystostomy case, passed through a Berkefeld filter and autoclaved and solutions of bile salts. The lesions produced in the pancreas by these methods of experimentation were brought about entirely through the action of the common duct sphincter, combined usually, first,

not always, with some increase of pressure. This increase in pressure need be very slight, indeed but little over normal bile pressure in the common duct, or may be even quite absent. This is the ordinary mechanism at work in human cases, even when gallstones are present. In these animals there was no question of any mechanical obstruction to the outflow of bile into the duodenum. The obstruction was purely a physiologic one. Most of the main types of lesion in the pancreas found in clinical practice were produced in this way. The experiments also seem to show very clearly that the necrosis of the pancreas is the direct result of the action of substances entering the duct of Wirsung, such as the bile salts, unmixed with bile colloids, or such as artificial gastric juice, or a whole series of acids and strong alkalies. Archibald believes that the extent of necrosis is determined at the very outset of the disease by the grade of virulence and extent of permeation of the noxious agent. Succeeding invasions of bile may increase the extent of necrosis. Liver necroses, of the type now well known as focal necroses occurring in the course of pancreatitis, were found with great regularity, both in fatal and in light cases; and were present within twenty minutes of operation. The severe cases with early death were all in the series in which infected bile was used. Sterilized mucin-free bile, and the bile salts in solution caused, it is true, necrosis of the gland, but a degree easily consistent with recovery; while the infected ox bile almost regularly caused early death, usually with, occasionally without, severe lesions in the pancreas. The surgical treatment of pancreatitis, Archibald says, must chiefly lie in a prevention of any further retrojection of bile into the pancreas. The damage already done to the organ will often be cured by the processes of nature, absorption, replacement, or even sequestration. On the other hand, if gangrene, abscess, or total slough has occurred, it may require a direct attack on the pancreas itself. But to prevent recurrence or extension the cardinal point would seem to lie in the prevention of any heightened pressure in the biliary system, and secondly in the restoration of an altered bile to its normal chemical condition, or of an infected bile to sterile bile. This can only be done by a drain in the gallbladder or in the common duct. The essential thing lies in prolonged drainage.

Treatment of Purulent Arthritis.—The history of cases of purulent arthritis of the elbow, knee and instep, due either to the diplococcus, staphylococcus or the streptococcus, with or without intra-articular fracture is given by Willems. These have been treated by simple arthrotomy followed by immediate active mobilization without any other means of drainage and without lavage. In all these cases drainage has been perfect, the temperature has not been high, the general state has remained excellent, infection has been confined to the synovia, there has been little or no atrophy, and articular mobility has been integrally preserved.

Röntgenographic Diagnosis in Renal Tuberculosis.—In Braasch and Olson's opinion the value of roentgenographic diagnosis of renal tuberculosis does not appear to be fully appreciated. They claim that shadows may be found in approximately 20 per cent. of patients with renal tuberculosis. Positive evidence of tuberculosis may be obtained by this method when all other clinical data fail, and when cystoscopic examination is impossible. Pyelography is occasionally valuable (1) in the identification of renal infections of doubtful nature and (2) in the identification of doubtful shadows in the renal area.

Vesical Sphincter After Prostatectomy.—A study of twenty-five cases convinces Watson that following perineal prostatectomy the internal or vesical sphincter returns to its normal tone and function in every instance within a few weeks.

Laparoplasty by a New Method.—The laparoplasty devised by Van Hook for relaxed, punching, or pendulous abdomens consists in raising two triangular flaps, points down of anterior rectus fascia and part of the external oblique muscle and fascia. The tip of the left flap is sutured over to the

right Poupart's ligament and pubis spine and vice versa in the case of the right flap. From a point in the median line about 1 or 2 inches above the symphysis pubic incisions to the right and left are made starting at right angles to the median line but, at the outer edge of the recti, turning upward and outward in the direction of the fibers of the external oblique muscle and extending to a distance of 6 or more inches on each side, splitting that muscle. Next, each of the triangular flaps thus produced, of which the apices point downward, is lifted carefully by separating the external oblique muscles (bearing their aponeuroses) up to the recti from the underlying internal oblique muscles. Then the anterior plates of the rectus sheaths are dissected up from the muscle bodies. These connective tissue membranes lifted off from the bodies of the muscles, leave the recti bodies in their normal beds. The raised rectus sheath flaps are now in continuity with the bodies and aponeuroses of the external oblique muscles. The next step is the crossing and reattachment of these flaps at points much lower than those to which they extended previously. The patient is placed in the Trendelenburg posture, then flex the knees and moderately flex the thighs on the abdomen, providing under the legs a suitable support. This diminishes the pressure within the lower abdomen, thereby relaxing the muscles of the abdominal wall and also, by anteriorly flexing the spine, lessens the distance between the ensiform cartilage and the pubic bone. The left flap is drawn downward to the right of the pubic bone, across the median line, until it is almost taut. It is carefully sutured to the aponeurosis of the right external oblique, to Poupart's ligament and the anterior sheath of the right rectus muscle at a level much nearer the pubes than that from which it was raised. The flap of the right side is similarly carried downward and to the left over the left rectus muscle and over the first flap and sutured in position. The skin and subcutaneous fat are extensively retranché and the T-shaped skin incision closed.

Acute Appendicitis Complicating Epidemic Influenza.—None of Behrend's patients gave a previous history of appendicitis. In one the appendix ruptured while in two pus was contained in the appendix. All the patients recovered. Five were not operated on because it was feared that the prevalence of rales in the lungs would eventually result in pneumonia. On account of "wet" lung the administration of an anesthetic was feared.

Exposure of Musculospiral and Posterior Intersosseous Nerves.—The authors describe three incisions for the exposure of the musculospiral nerve from the lower border of the teres major muscle down to the antecubital fossa. The first incision lies in a line from the tip of the olecranon to the posterior angle of the acromion. It begins three fingers breadth below the acromion and continues directly downward along the above line to 5 centimeters below the level of the insertion of the deltoid. The second incision runs parallel to the first except in its lower part, where it is slightly curved toward the anterior side. It begins about 12 centimeters above the antecubital fossa external to the brachialis anticus and between it and the almost longitudinal fibers of the supinator longus. The third incision is made midway between the other two and parallel to the first. It should extend from 3 centimeters above the level of the insertion of the deltoid directly downward for about 12 centimeters.

Tendon Transplantation.—In the operative treatment of nerves and paralyzed muscles Starnage and his associates have been guided by the work of Robert Jones on poliomyelitis, and they have successfully applied his methods of tendon transplantation and fixation in cases in which failure for nerve suture, or in cases in which nerve suture had failed. This operation has been carried out for three types of nerve injury: (a) Irreparable injury to the musculospinal nerve with wrist drop; (b) similar injury to the median nerve; (c) injury to the musculocutaneous nerve in the leg with paralysis of the peronei muscles and resulting pes equino varus.

Hydrocarpic Acid in Leprosy.—As Roger's experiments have indicated that the sodium salt of hydrocarpic acid is probably most active in leprosy, he has treated a further series of cases with a preparation made of Hydriocarpus wightiana oil consisting mainly of sodium hydriocarpate with sufficient of the lower melting point acids to make it soluble, but also containing a little sodium chaulmoograte, as these acids are so closely related that they can only be separated in pure form by very prolonged fractionation. This preparation, as well as that which in former papers was called "sodium gynocardate A," is now referred to by the more correct term hydriocarpate of soda. The great reduction in the numbers of the lepra bacilli before and after treatment and their frequent total disappearance is a very satisfactory feature of the series, while the number of cases in which lesions disappeared in less than a year is also noteworthy. In only one of fourteen cases was but slight improvement obtained.

Margoate in Skin Lesions.—Chatterjee details the results obtained in the treatment of cases of syphilis, leprosy, skin disease, filariasis, septic infections and ulcers with ethyl ester margoate and hydriarytri margoatits. The experience has been very satisfactory.

Infecting Agent in Influenza.—Yamamoto and his associates report on their experiments made to find the exciting cause of influenza. An emulsion of the sputum from forty-three influenza patients was made in Ringer's solution. This emulsion was injected into the nose and throat of twelve healthy persons. A filtrate (by Berkefeld filter) of the same emulsion was injected into the nose and throat of twelve other healthy persons. Among the subjects treated were six persons who had already had influenza, and all six were free from symptoms of illness. But all of the other eighteen subjects, both those who had received the emulsion and those who had received only the filtrate were attacked by the disease, after an incubation of two or three days. Their fever was sometimes slight, sometimes very severe. The subsequent symptoms were headache, sore throat, lumbago, cough and the like. A filtrate of blood of influenza patients was injected into the nose and throat of six more healthy persons. The results were precisely the same as in the previous experiments. The authors inoculated subcutaneously four healthy persons with the filtrate of the sputum emulsion and four others with a filtrate of the blood of influenza patients. They all, with the exception of one who had previously had influenza, developed the disease after two or three days' incubation. A pure culture of Pfeiffer's bacillus and a mixed preparation of the pure Pfeiffer bacillus, along with pneumococci, streptococci, staphylococci, diplococci and many other like microbes common in the sputum of influenza patients, were injected into the throat and nose of fourteen healthy people who had not had influenza. There were no symptoms of illness following these injections.

Treatment of Bone Sinuses by Solid Metal Drains.—Symonds uses both hollow and solid metal drains in the troublesome sequelae of fractures and gut-shot injuries. The metal prevents closure of the orifice. It also rapidly reduces the septic changes, and by preventing retention of pus, with consequent decomposition and infective osteitis permits the formation of new material and closure of the cavity. The rod is smooth, has a rounded end, and can be removed and inserted without any injury. When substituted for gauze the beneficial effects are at once evident in the disappearance of the surrounding dermatitis and marginal granulations and the decrease in the discharge. Pain, where existing, rapidly subsides and very soon a retraction of the orifice is seen. Symonds uses a glass rod, bent to any desired angle.

Blood Transfusion by Citrate Method.—After having used this method in 100 cases Fleming and Porteous are convinced that it is as good as those of any of the more complicated and difficult methods.

New Method of Incision of Tympanic Membrane.—Lake makes a cross-centric or curved incision following the contour of the edge and of about the same extent of the posterior superior quadrant, i. e., a curved incision with the convexity upward. He claims that better drainage is obtained.

Intrathoracic Pressure in Hemothorax, Etc.—According to Shattuck and Welles fluid or air in the pleural cavity reduces the normal negative pressure and may convert it into a positive pressure. The degree of reduction of intrathoracic pressure depends on the volume of fluid or air or of both in the cavity. Small hemothoraces do not give positive mean pressures. Large hemothoraces of hemopneumothoraces may do so. The pressure in a sterile hemothorax changes little during the first sixteen days after wounding. The respiratory excursion of pressure in small hemothoraces increases gradually during the first sixteen days after wounding. The respiratory excursion in large hemothoraces is less than in small ones. The excursion seems to be greater when there is air in the pleural cavity than when there is fluid only. Pressures observed in pleural effusions were similar to those in hemothorax. By simultaneous replacement of fluid withdrawn by oxygen volume for volume, existing pressure in the pleural cavity can be maintained.

Contralateral Signs in Gunshot Wounds.—When first taking up the study of gunshot wounds of the chest Curl says he was forcibly impressed by the apparent great frequency with which, in the case of injury to one side, abnormal signs were to be found on the uninjured side. He groups the cases presenting contralateral signs as follows: 1. Those with contralateral pleurisy. 2. Those with contralateral pneumonia. 3. Those in which no clear evidence of pneumonia exists and in which the presence of râles forms the chief, if not the sole, contralateral sign. 4. Those in which the physical signs suggest a condition of consolidation or condensation of lung tissue and do not conform to any of the preceding conditions. Up to the early part of this year Curl's series of sixty cases presented twenty-nine contralateral signs of one kind or another, as follows: Pleurisy in four cases; pneumonia in four cases; râles in seven cases; signs suggesting pulmonary consolidation or condensation, with or without the presence of râles in fourteen cases.

Two Cases of Endocarditis Due to *Influenza Bacillus*.—A man, aged 39, was admitted to the hospital on the third day of the disease with a diagnosis of bronchitis. He had dyspnea and pain in the right side of the chest with signs of consolidation of the right lung and of left base. His case was diagnosed on the sixth day as lobar pneumonia, but the diagnosis was changed on the twelfth day to confluent influenzal bronchopneumonia because of the finding of *B. influenzae* as the predominating organism in the sputum. Examination of the heart was negative. The temperature was subnormal with rapid respiration and pulse. Heavy sweats. Death on thirteenth day. Postmortem examination showed bilateral confluent bronchopneumonia; dilated right heart, syphilitic aortitis also involving aortic ring; acute vegetative endocarditis of aortic cusps; mild chronic interstitial nephritis. *B. influenzae* was grown in pure culture from the terminal bronchioles, from the heart's blood, and from vegetations on the aortic cusps. Another man, aged 44, was admitted on the fourth day of the disease, with a diagnosis of bronchopneumonia. Onset with chill after getting wet. The man had cough, pain in the chest, dyspnea, cyanosis, signs of capillary bronchitis. The case

was diagnosed as influenzal bronchopneumonia because of the nummular character of the sputum and the presence of *B. influenzae* as the predominant organism in it. The heart was enlarged but no murmurs were heard. Dyspnea and cyanosis increased; sweats, "septic" temperature, death on sixth day. Postmortem examination showed a bilateral capillary bronchitis and bronchopneumonia; dilatation of the right heart, hypertrophy of both sides; an old endocarditis of the aortic cusps (slight); acute vegetative endocarditis of the aortic cusps and on otherwise healthy mitral cusps; large "septic" spleen; slight chronic interstitial nephritis. Cultures from the terminal bronchi and from the center of the aortic vegetations yielded *B. influenzae* in pure culture. The culture from the heart's blood was negative.

Therapeutic Action of Digitalis.—A study of the effect of digitalis in these cases has convinced Sutherland that this drug can be used with as much confidence in its efficient and beneficial action as in cases of auricular fibrillation. In the former digitalis is given with a view to its action on the sinoauricular node, while in the latter its action is directed to the auriculo-ventricular node and bundle. In both cases a slowing of the ventricular rate is aimed at and provided that there is a sufficiency of sound contractile tissue in the ventricles, the natural powers of the heart are capable of restoring a weakened or failing circulation.

Acute Leukemia and Mediastinal "Leukosarcomatosis."—In only one of six cases of this disease was Weber able, by the help of roentgen-ray examination and by the microscopic blood picture, to make the diagnosis during life. The boy was admitted to the hospital with fever, respiratory distress, and ascites, and was at first supposed to be suffering from tuberculosis. However, his extreme pallor and the presence of cutaneous petechiae suggested an examination of the blood, which revealed the leukemic blood picture. Owing partly to his peculiar dyspnea a roentgen-gram of the thorax was taken, and this showed great shadowing at the base of the heart, suggesting the presence of a tumorlike mass in the mediastinum.

Two Cases of Diabetes Insipidus.—Data are given by Kennaway and Mottram as to the composition of the urine, and its molecular concentration in comparison with that of the serum, in two cases of diabetes insipidus. When large amounts of sodium chloride are given, the diuresis is so adjusted that the percentage of nitrogen plus chloride in the urine remains unaltered; the kidney, therefore, lacks the power of concentration which is exhibited normally after the ingestion of salt. The antidiuretic effect of pituitary extract given by subcutaneous injection was demonstrated both in a normal subject and in a case of diabetes insipidus; administration of such preparations by the mouth is ineffectual. No record has been found by the authors in the literature of any case of diabetes insipidus in which abnormality of the pituitary was excluded with certainty by postmortem examination, whereas in a considerable number of cases the disease has been associated with a lesion of the posterior lobe of the gland. However, such lesions are not invariably accompanied by diabetes insipidus. The evidence of morbid anatomy as to a connection between the pituitary gland and diabetes insipidus is therefore inconclusive, but the immediate restoration of a normal state of the urine when pituitary extract is given in diabetes insipidus provides the strongest evidence for the normal activity of the gland in regulating the secretion of urine.

Filter Passing Virus of Influenza. The result of the experiments described by the authors, it is claimed, establish that all the lesions of influenza have been reproduced in animals by the injection of pure cultures of an agent isolated from man, and they fulfill all the requirements necessary to establish that organism as the cause of the disease. In the first place, the disease was reproduced in attenuated form as in poliomyelitis. The increase in virulence by passage so that, e. g., the mortality in glabral inoculations rose from a probable four in six to a real mortality of three in three, and perhaps the small effects produced in all pigs removed for the third time may have

a bearing on the greater severity of late phases of the present epidemic. The success of subdural inoculation and the rapidity of onset thereafter may give support to the opinion that the organism finds entrance to the body via the nasopharynx, but does not exclude other means of entrance. The numerous sites in which the organism is found in the body, and its presence in the bile and kidney and also the urine of monkeys, show that the nasopharyngeal mucus is not the only channel of its excretion. The prolonged residence of the organism in the tissues may likewise be of epidemiologic significance in the production of strains of heightened virulence. The authors point out that influenza should no longer be regarded as primarily a disease of the lungs. The process is exactly the reverse. The lung is not attacked through the air passages by a gradual extension downward from the higher respiratory passages to the alveoli. The lungs are attacked from within the body through their entire vascular mechanism from the blood stream, in company with other organs in varying degree. Masses of dead or disorganized tissue and blood clot and the disorganization of respiration soon provide not only fuel for local secondary infective processes, but also means by which the secondary infections, in their turn, come to produce septicemia on their own account by a reversal of the process in an individual weakened by the primary disease. An organism, of definite morphologic and cultural characters, has been isolated by the authors from cases of influenza. It can be demonstrated in the blood, sputum and other exudates, and in the tissues, postmortem, by appropriate methods of staining. It belongs to the group of "filter-passers," a group of organisms which pass through bacteriologic filters. It has been seen microscopically in the filtrate and has been cultivated therefrom. It has not been found in a large series of controls.

Bulletin de l'Académie de Médecine, Paris

May 15, 1919, 81, No. 19

- *Cesarian Section.—Guéniot, p. 637.
- *Radium Treatment of Ear, Nose and Throat Tumors. Lannois, A. Sargens and Moutet.—p. 638.
- Normal and Pathologic Cytology of Salivary and Parotid Glands.—De la Prade and Tourt.—p. 645.
- *Gasserectomy for Neuralgia. J. Perrier.—p. 645.
- Hemostatic Apparatus of Uterus. H. Joly.—p. 650.

Cesarian Section.—Guéniot recalls 138 complications in 1870 of the cases of cesarian section to date. He was able to find records of only 6 authentic successful cases during the eighteenth century, and not one successful case to that date in the nineteenth century among the 40 cases that had been published. Only one of the patients survived to the eighth day and then succumbed to tetanus. Bar has recently reported a series of 97 cases without a single mishap. Guéniot has not been so fortunate, as 4 of the 11 women died in his cases, but some of them were emergency operations. He lauds the advantages of planned cesarian section just before term, preparing the patient as for any laparotomy. He warns that we must not let labor surprise us, and advises to incise the fundus rather high, and drain into the vagina with a large stiff tube for five or six days, raising up the uterus as needed. He warns further that with extraordinary need methods of cesarian section if there is preexisting infection, or infection develops later, it is just as redundant here as if the peritoneum were infected, while the technique is more complicated. Hence he advises against any modification of the old and tried high technique.

Radium Treatment of Tumors in Ear, Nose and Throat. Lannois and his co-workers compare the outcome in their 43 cases with other experiences. They realized with the radium a clinical cure in 6 of 16 cases of malignant in situ of the tonsil; in nearly all of 6 cases of cancer of the nose, in 4 of the nasopharynx, and in 2 of 3 cases of ear cancer. The sarcoma cases were the ones most favorably influenced. Epitheliomas proved more persistent, and as cancer of the larynx is usually of this type, they have only 3 successful cases to report in their 14 cases in this group. The so-called ulcerating epitheliomas are the most refractory. Epitheliomas

of the ectodermic type with *globe corne* are scarcely amenable to radium treatment; the results are often bad. Their method is to use as large a dose as possible, from 30 to 120 mg. of the radium bromid, and they left the tube in place at least twenty-four hours, sometimes thirty-six or even forty-eight hours. They aim to strike as hard as possible. If a second application is necessary, they postpone it as long as possible on account of danger of burns. One boy of 12 with a fibrosarcoma of the nasopharynx was given three exposures in two and a half months. Two months after the last application, after all traces of the tumor had disappeared, perforation of the hard palate occurred. This was the only grave complication in their experience, but in three cases of epithelioma of the tonsil the uvula dropped off. The radium burns are generally insignificant although they may sometimes entail gangrene, especially in the larynx, so that they found it best to reduce the dose for the larynx. They comment on the great advantage of using emanations, needles or in place of tubes coated with the emanations.

Gasserectomy for Trigeminal Neuralgia.—Bourguet has had patients whose trigeminal neuralgia returned after local injection of alcohol and the intense pain persisted in spite of systematic alcohol treatment. Gasserectomy was the last resource and cured them once for all. He advises access through a curved incision in the temporal bone. This exposes the maxillary nerves and these, like Ariadne's thread, lead directly to the gasserian ganglion. It is not necessary to resect the zygoma, etc.; he merely divides the dura mater and severs the middle meningeal. When the gasserian ganglion is reached, he cuts the fibrous connections between the gasserian ganglion and the dura mater. Unless this is done, some of the ganglion is liable to be left. Neuro-paralytic keratitis developed afterwards, but this is liable after any operation of the kind, even after Frazier's more complicated technique, and the keratitis yields promptly to treatment.

- Arterial Bacterial Meningitis. D. Leter and C. Dubois.—p. 332.
- Types of Prevalent Meningococci. Netto, Moser and J. Fabianer.—p. 334.

Lethargic Encephalitis.—Audbert's patient developed typical lethargic encephalitis at Marseilles, and the disease has been encountered in Algiers, Belgium and at Athens. Netter refers also to Morquio's three cases in children at Montevideo. One youth at Athens who finally recovered was left totally blind.

Hypothermic Influenzal Pneumonia.—The temperature kept between 35.6 and 36 C. (96.1 and 96.8 F.) and one of the men died.

Endocarditis During Influenza. Du Castel and Dufour relate that after a few days of typical influenza, pneumonia developed, with latent endocarditis and a final phase of embolism, with death in about two weeks from the first symptoms.

Dragging Apex Beat.—Jomier noticed that the apex beat seemed to be protracted in 43 of the men examined, and in 30 in this group there were signs of valvular disease. In only 4 of the total 43 was the heart apparently normal. A dragging apex beat should always suggest valvular disease, especially when pronounced. The mitral valve was pathologic in 24 of the 30 valvular cases, the aortic valve in 6.

Rabies.—The girl of 14 whose case is described in detail by Lesieur, Lhermitte and Jacquet had the bullbar form of rabies, with especially pronounced distress, actual anguish. The latter preceded by several days the organic manifestations. They regard this sensation of anguish as a characteristic bullbar phenomenon. In some of the paroxysms of anguish it seemed to comprise the whole disease, as if it were to rabies what the muscular spasm is to tetanus. In this case the rabies developed nearly three months after the child had been bitten. She had been given systematic antirabies treatment, commencing fifty-three hours after the bite of the rabid dog. Netter reported a similar case in which the agitation, distress and periods of delirium had preceded by eleven days all the other symptoms of rabies. The boy of 11 had been bitten in the cheek two months before by a small dog with which he was playing and which later disappeared.

Anthrax Meningitis.—The anthrax had not been diagnosed during life as the pustule had not had time to develop its characteristic form. It was on the left cheek and the edema around was ascribed to phlebitis of the jugular vein. The young man, an American soldier, died the second day with symptoms of fulminating meningitis, and anthrax bacilli were found in the cerebrospinal fluid.

- *Chronic Pseudo-Appendicitis. R. Grégoire.—p. 379.
- *Skin Complications of Exophthalmic Goiter. J. du Castel.—p. 382.
- *Case of Superficial Leishmaniasis in Algiers. G. Heuyer and L. Cornet.—p. 385.

Treatment with Condensed Radium Emanations.—Regaud is director of the biology laboratory in the Radium Institute, and he here outlines what is known in regard to radium treatment and expatiates on the great clinical importance of tubes of condensed emanations and their numerous advantages.

Chronic Pseudo-Appendicitis.—Grégoire analyzes the lesions in or around the ileum, cecum and colon which may simulate chronic appendicitis. In some of the cases he describes the appendix had been removed and nephrectomy done but the symptoms still persisted. Radioscopy usually shows the right colon much dilated, and that it is bound down and more or less kinked and obstructed. The fibrous bands responsible for this may be of inflammatory origin or congenital, and after freeing the bowel from its hampered condition the pains and constipation subside as a rule, but not invariably. Certain points are still obscure in these pseudo-appendicitis cases, as not every subject is absolutely cured by this surgery of the colon.

Skin Complications of Exophthalmic Goiter.—Du Castel passes in review the vasomotor, trophic, toxic and microbial complications which may develop with latent or manifest exophthalmic goiter. Certain eruptions, pyodermatitis or eczema may display a chronic or recurring tendency which finally is explained by development later of symptoms of exophthalmic goiter. The part played by the soil in these cases should be better appreciated.

- *Diagnosis of Amebiasis. C. Mathis.—p. 399.
- *Peritoneal Reaction in Secondary Malaria. F. Trémolières and G. Leclerc.—p. 398.
- Oscillations in the Blood Pressure. F. Lévy.—p. 399.

The Ameba in the Stools.—Mathis discusses the technic for the search for entamoebae and their differentiation from other parasites. Five illustrations show the parasites with which it is most liable to be confused.

Peritoneal Reaction in Malaria.—Trémolières and Leclerc describe the acute peritoneal reaction in the course of secondary malaria. In one case described the man of 36 developed symptoms simulating peritonitis from perforation of a viscus. The reaction was most pronounced in the liver region, and the liver was large and painful. There was nothing except the secondary malaria to explain this perihepatic reaction and warn against operative measures.

- *Gastric Cancer. H. Hartmann.—p. 45.
- *Sign of Organic Radial Paralysis. J. Bousquet.—p. 247.
- *Pathogenesis of Influenza. A. Orticelli, Barbé and Ayce.—p. 241.
- *Early Treatment of Syphilis. M. Pinard.—p. 249.
- *Cure of Leg Ulcers and Edema. V. Audibert and Fougère.—p. 241.

Cancer of the Stomach.—In his general review of this subject, Hartmann cites statistics showing the constantly increasing proportion of permanent cures after operations for gastric cancer. He has been able to trace 3 of his own patients cured for five years, 3 for six, 2 for seven and 1 for thirteen years, although he has lost track of the majority of his cases.

Differentiation of Organic Radial Paralysis.—Bousquet's illustrations show a characteristic inability to spread the fingers apart on a plane surface when there is organic radial paralysis. The first phalanx of the fingers curves and the thumb twists in abduction. With hysteric radial paralysis, either the patient is unable to make any spreading movement or it duplicates the action of the sound side.

Pathogenesis of Influenza.—Orticelli and his co-workers regard it as significant that there was an extensive epizootic among horses at the time of the epidemic of influenza last year. They isolated from the blood of some of the horses a bacillus which seemed to be identical with the bacillus they had isolated from the blood of some of their influenza patients, namely, an aerobic nonmotile coccobacillus, with long and short forms, and not growing on bouillon and gelose. They recall the severe epizootic in horses in 1889, and say that the present epidemic resembles it, only that the pulmonary complications were more severe in the epidemic of last year. In some of the neighboring villages all of the horses were coughing at the time the influenza was affecting the populace.

Abortive Treatment of Syphilis.—Pinard reports that in his experience as chief of the Centre dermatosyphilitographique at Versailles, early treatment with mercury or neoarsphenamin did not always ward off the development of lesions in the skin and mucosa. They are infinitely rare, however, after arsphenamin treatment. Meningeal lesions are liable to develop after any treatment when it is not thorough enough. He warns against danger when mercury and an active arsenical treatment are given together. There does not seem to be any danger with the technic he advises, namely, six injections of a total of 2.30 gm. arsphenamin in not quite a month, beginning with 0.10 gm.; after three days, 0.20; after four days, 0.30, and then every seventh day, 0.50 or 0.60 gm. Absolute eradication of the disease seems to be possible, judging from some of his cases of ten years' standing, but this is based on empiric findings alone.

Treatment of Leg Ulcers.—Audibert and Fougère comment on the ease and rapidity with which edema and chronic ulceration on the legs can be cured by a gently compressing medicated bandage. They wind the leg from the root of the toes upward with a stout roller bandage dipped in the creamy mass formed by mixing 10 gm. each of gelatin, zinc oxid and starch with 40 gm. each of glycerin and water and adding 100 gm. potassium silicate. The strips of stout gauze impregnated with this are softened in hot water when ready to use. The dressing is renewed every four days, and the patient is encouraged to walk and use the leg freely, as this breaks up the vicious circle from the stasis and defective nutrition of the parts from disuse of the limb. An illustration shows a ten year ulcer on the leg. It is shown again, completely healed, after six applications of the stiff dressing, in the course of thirty-one days. Healing is usually completed from two to eight weeks, and the method has never failed yet. The use of the leg keeps up a continual massage of the veins and tissues, and expels the toxic serum finally absorbed in them. W. King is therefore an indispensable element in the treatment. The ulcer heals in its own progress, but attention is diverted from his ulcer by the roomy dressings, so that his work rendered possible by the dressing on the legs, and his spirits go up when an only one is put on him, which can be safely done. In other cases it is contraindicated.

May 12, 1919, 27, No. 27

- *The Masters of Physiology. C. Richet.—p. 257.
 *Surgery to Remove Wrinkles. R. Passot.—p. 258.

The Masters of Physiology.—Richet's address on the pioneer research of Descartes and Lavoisier was delivered by request to the American medical students now studying at the Paris Faculté de Médecine.

Surgery to Correct Wrinkles.—Passot's illustrations show how it is possible to smooth out wrinkles by cutting out an ellipse of skin close to the edge of the hair. As the lips of the ellipse are sutured together, the slack in the skin causing the wrinkles is taken up, and the skin lies smooth. The wrinkles at the corner of the eye require two small ellipses, one close to the hair above, the other just below and in front of the lobule of the ear. Double chin can be corrected in the same way with a long "cravat" resection of skin in the neck below. The adipose tissue is removed, down to the aponeurosis, in resecting the ellipses. The ultimate outcome in some cases operated on by Pozzi, Martel and Morestin some years ago has been gratifying, and Passot has now a record of fourteen operations for this esthetic purpose. The effect is often rejuvenating to the spirit as well as to the outward appearance. Each case has to be studied by itself, taking up folds in the skin to see where traction is most effectual. When the best fold for the purpose is located, he holds it by gentle pressure from several forceps or clothespins, and marks around the base with a skin pencil, marking also with a compass the exact points for coaptation in suturing. The geometrical figure thus drawn on the skin is usually an ellipse 3 or 4 cm. long by 1.5 or 3 cm. wide, but it may be oval, the small end the upper one. The sutures are subjected to strain from laughing, yawning or even chewing, and to protect them he fastens a transparent shield with collodion in such a way that the traction comes on the shield more than on the suture. The subcutaneous skin is pulled up and the collodion applied low down so that the edge of the shield is fastened to the skin some little distance below the actual suture. The resection of an ellipse, in front of the lobule of the ear tends to smooth out wrinkles all over that side of the face, and is usually necessary whatever other ellipses may be resected. When the ellipse is cut too high, the outer angle of the eye is liable to be drawn out of place. The desire to conceal the scar in the hair has led to this disfigurement in cases he has seen operated on by others. The whole success depends on the care used in taking up the most effectual fold. If in time the skin sags into wrinkles anew, the correction can be repeated. He adds that the war has brought to the fore surgery of the face, and esthetic surgery should take the place it deserves.

- *Surgery of the Knee. J. L. Roux-Berger.—p. 267.
 *The Cupping Glass Test in Eruptive Diseases. D'Oelsnitz.—p. 268.
 *Indication of Vision in Treatment of Strabismus. A. Contoret.—p. 274.

Surgery of the Knee.—Roux-Berger refers to traumatic lesions of the knee, giving illustrations of the principal types and the special treatment each requires. In one of the cases described by opening up the joint wide disclosed the partial fracture of the cartilage and a loose scrap of cartilage. In less than four months after the arthrotomy, the young man was able to play football.

The Cupping Glass Test in Eruptive Diseases.—D'Oelsnitz uses a vacuum glass with rubber bulb as a form of revulsion which aids in the differential diagnosis of eruptive diseases. It is particularly instructive in measles, especially where troops are congested. The measles or scarlatinal eruption is brought out plain by it in suspicious incipient cases. Even premature desquamation may be brought on. This test always gave negative findings with eruptions of alimentary origin, and, in his experience, always in rubella. This test also reveals a hemorrhagic tendency before it has become apparent in other ways.

Enteroneuritis.—A practically identical article by Loeper was summarized on page 1795.

Occlusion of the Intestine for Eleven Years.—Barbier's patient was a woman of 38 and for eleven years the feces had merely piled up in the colon, the mass of the "Fecaloma" filling almost the entire abdomen. And yet during the last year she had passed through an apparently normal pregnancy. The only mishap during the pregnancy was a menace of peritonitis three weeks before delivery. It was averted, however, by application of ice. Colic, vomiting and diarrhea ushered in the disturbances at the age of 23 and paroxysms of pain occurred regularly every ten or fifteen days, but the proposed operation was constantly refused, until the attacks became unbearable. The colon was sutured to the laparotomy incision and every morning for several weeks some of its contents were scooped out. By the end of the third week the colon could be drawn out and the segment with the stenosis was resected. There was no ulceration above but the wall of the intestine had grown very thick.

Correspondenz-Blatt für Schweizer Aerzte, Basel

May 3, 1919, 49, No. 18

- *Principles of Disinfection. W. Sittler-Schmidt.—p. 593.
 *Medical Experiences in Asiatic Turkey. A. Vischer.—p. 601.
 *Film Treatment of Wounds. J. de S. Palma.—p. 619.

Medical Impressions in Asiatic Turkey.—Vischer served for nine years as chief of the German Oriental Mission Hospital at Urta in northern Mesopotamia. From 3,811 to 5,991 patients were cared for each year. Tuberculosis was prevalent and the pulmonary form seemed to run an exceptionally rapid course. Goiter was unknown at Urta but he saw several cases at Diarbekir, about 150 km. to the northeast, on the Tigris. Appendicitis was also extremely rare, but hernia and bladder stone operations were comparatively numerous. The infant mortality was 46.6 per cent. among the children of 317 women investigated (1,803 infants). Typhus and scarlet fever were never seen, and only one case of diphtheria. Every one without exception seems to have typhoid, sooner or later. Venereal diseases are common but the nervous system seems to escape. No instance of rabies was encountered. In 1913 there was a severe epidemic of acute poliomyelitis.

Film Treatment of Wounds.—Palma does not refer to paraffin films but to a tannin-gelatin-borax preparation which has been styled a "wound cement." He has been experimenting with various chemicals striving to promote local leukocytosis and phagocytosis while preserving the cement film action. Turpentine and calcium chloride are among the chemicals which display this action even in minute amounts.

Gazzetta degli Ospedali e delle Cliniche, Milan

April 17, 1919, 40, No. 31

- *Pneumothorax Complicating Influenza. G. Massaro.—p. 282.
 *Treatment of Chronic Empyema. G. Onano.—p. 284.

Chronic Empyema.—Onano makes an incision, close to the sternum, over the rib and only as long as the rib is wide. The rib is then sawed with a Gigli saw. This is repeated with several of the ribs, leaving a space of intact skin between them. At the back, a paravertebral incision permits partial resection of the scapula. Then a compressing bandage is applied, after providing for drainage above and below, and the whole side of the chest sinks in enough to break up the vicious circle and start the healing process. The results have been most encouraging.

April 20, 1919, 40, No. 32

- *Wide Variability of the Same Infections in Different Individuals. U. Eberlein.—p. 289.

Variability of Same Infection in Different Persons.—Bacillus varius that in the prevailing zeal for bacteriology we overlook the importance of the biochemical condition of the

subject and the importance of the ambient as decisive factors in the disease. These latter determine the orientation and the clinical form of the disease and impress it with the individual stamp.

Policlinico, Rome

May 11, 1919, 26, No. 19

*The Clinical Value of Occult Blood in the Stools. D. Maselli.—p. 577.
Silver Nitrate in Treatment of Mustard Gas Lesions. G. Amantea.—p. 590.

The Hemorrhagic Diathesis. Lino Urizio.—p. 592.

Occult Blood in the Stools.—Maselli remarks that to date we have no absolutely specific chemical test for blood in the urine. All the techniques in vogue give a positive response with certain other substances besides blood. Microscopic examination of the stools will sometimes reveal substances to which the positive response might be credited. It is not safe to draw conclusions from positive findings unless different techniques and repetitions of the tests give concordant responses. A negative response with the benzidin test, when strictly applied and to different parts of the stool, may be regarded as decisive as to the absence of blood from that particular stool.

Riforma Medica, Naples

April 26, 1919, 35, No. 17

*Meningeal Reaction in Paratyphoid. E. Maragliano.—p. 334.

*Desiccated Antigens for Serodiagnosis. Micheli and Satta.—p. 337.

*Fourth Centenary of Leonardo da Vinci. A. Anile.—p. 339.

Normal and Deformed Feet. E. Aveoloni.—p. 343.

Meningeal Reaction in Typhoid and Paratyphoid.—Maragliano warns to be very cautious in pronouncing the word meningitis in the course of typhoid and paratyphoid. A simple and comparatively harmless meningism may be pronounced for symptoms which deceptively simulate true meningitis.

Desiccated Antigens for Serodiagnosis.—Micheli states that three years of experience with desiccated antigens has confirmed their reliability for diagnostic purposes. The bacteria are dried in a vacuum at room temperature, and a suspension of the dry cake thus obtained is made when ready for use. The biologic and biochemical properties of the antigens do not seem to be modified by this procedure. He has thus prepared antigens for the meningococcus, streptococcus and a long list of other infections, including dysentery and typhoid. These desiccated antigens keep indefinitely. The bacteria seem to maintain a latent vitality; it can be aroused by making an emulsion with bouillon and inoculating for thirty-six or forty-eight hours. Typhoid and paratyphoid bacilli were thus roused to life anew after an interval of two years, and dysentery bacilli after five or six months.

The da Vinci Quadricentenary.—Leonardo da Vinci died May 2, 1519, and this quadricentenary has brought a new revision and appreciation of his scientific work. He is said to have written 120 books on anatomy alone, commencing at the age of 37. Most of these have been lost, but enough remains to show his indefatigable zeal in reproducing in drawings what he saw in the thirty cadavers he was able to secure at different times until the authorities definitely excluded him from the hospitals at the age of 61. Anile declares that the drawings are so perfect that even after four centuries of research on anatomy and physiology there is nothing to add to them, and in certain points they actually suggest whether our present conceptions may not be erroneous. His drawings are the more remarkable when we realize that they were done practically clandestinely, with poor illumination and no means of preserving the cadavers from rapid decomposition. In preparation for celebration of this anniversary in Italy an effort has been made to collect his scattered works, with photographic reproductions of others in the various libraries of Europe.

*Sterilization during Cesarean Section. S. Della Chie.—p. 355.

*Function of the Deciduous Teeth. C. D'Alis.—p. 359.

Sterilization During Cesarean Section.—Della Chiea declared that it was necessary to prevent further pregnancies

in five of the fifteen cases in which he delivered the women by cesarean section. He accomplished the sterilization at the time of the cesarean section by cutting the tube at the cornu of the uterus and transplanting this end of the tube into a buttonhole made for it in the uterine wall, with care not to injure the round ligament or perforate the wall. The stump of the tube was held in place in this buttonhole with a few silk stitches, and the same procedure was repeated on the other side. The operation is thus an actual salpingo-uterus anastomosis, like Watkins' technique, only Della Chiea does not resect the tube as Watkins does. Mere ligation of the tube does not guarantee against conception later, as he found in one of his cases, and as others have reported. At a later cesarean section he saw that the catgut used for the two ligatures had evidently been absorbed too soon. The women treated with the salpingo-uterus anastomosis have shown no signs of conception during the two and three years since to date.

*Pathologic Anatomy of Lymph Glands. O. H. Reelley.—p. 128. (Cont.)

*Amebiasis of the Lung. L. B. Sanchez.—p. 138.

The Pelvis in Peruvian Women.—Romero states that the measurements of 1,115 women showed an average of 12.60 per cent. with abnormal pelvis although some in this group had apparently normal pregnancies and deliveries. The conjugata vera never measured less than 7.5 cm. He lists the various types of abnormal pelvis as encountered in the last four years.

Tests for Blood in the Urine.—Velasquez describes and compares different techniques, expatiating on the simplicity and reliability of the Thevenon and Rolland method. He has applied it on an extensive scale, and found it extremely instructive for determination of blood in all the body fluids. Three reagents are required: (1) 2.50 gm. dimethylaminopyrrolone (pyramidon) in 50 c.c. of 90 per cent. alcohol; (2) 2 c.c. of glacial acetic acid in 2 c.c. distilled water, and (3) hydrogen dioxide (12 volumes). To 3 c.c. of the unfiltered urine are added 3 c.c. of solution 1 and 6 drops of the acetic acid solution, and the tube is agitated. Then, on addition of 3 drops of the hydrogen dioxide, in less than fifteen minutes the tint veers to a bright violet which only slowly disappears.

Pulmonary Amebiasis.—Sanchez diagnosed congestion of the base of the left lung from the hemoptysis and other symptoms presented by the wood-cutter, 48 years old. Under repose the fever subsided, but the blood streaked expectoration and the stethoscopic findings persisted unmodified or more pronounced. Cysts of the *Entamoeba histolytica* were found in the sputum repeatedly, even after a course of treatment by the vein, but the general condition improved notably on this treatment. Sanchez thinks there can be no doubt that the amebas were directly responsible for the hemoptysis.

Methylene Blue in Influenza. J. M. Busa—p. 45.

Artificial Joint to Correct Ankylosis.—Lozano has experimented on dogs with complete success interposing an artificial joint after resection of the natural joint. He makes it on the principle of a bone and socket joint. A solid sphere like the head of the femur, 10 mm. in diameter, with a stout pedicle, is mounted on a small plate with four branching arms. On a second similar plate is mounted a corresponding hollow sphere in which the first sphere fits smoothly, but can be moved freely in every direction. The bones were resected in the ankle region and this artificial joint was implanted, the four arms on each half being bent back over the stump, and held in place with wire passing through tunnels hollowed out for the wire in each of the arms of the plates. The dog still limps a little, but in running and jumping the limp is scarcely perceptible, and the region of the new joint is not tender on pressure. The artificial joint is made of gold and platinum. The soft parts are scrupulously respected, and the interposed artificial joint answers its purpose perfectly. It fits on the horizontal bone stumps without the necessity for boring into the bone. The nature of the ankylosis generally requires resection such as this, the bones perfectly for this artificial joint. Several illustrations show the mechanical detail, and roentgenograms are given of the dog's leg.

Technic for Amputation of the Leg. A. A. Alsina—p. 11.
Etiopathogenesis of Typhus. R. Kraus—p. 317.
Lean Diabetes. P. M. Barlow—p. 319.

Amputation of the Leg.—Alsina gives twenty illustrations to show the preferable technic for amputation at different heights. He advises to saw the fibula an inch higher than the tibia, and to provide a large posterior or antero-external flap.

Serodiagnosis of Typhus. Kraus describes the application of the agglutination test with a strain of proteus during the recent public health expedition to foci of typhus in two remote provinces. An alcoholic preparation of the proteus was used, and he comments on the advantages of this durable preparation. Two agar slants of the proteus N 19 were emulsified with 2 c.c. of saline, and to this was added four times the volume of absolute alcohol and it was set aside for an hour, then centrifuged, the alcohol decanted, the sediment emulsified in an amount of saline equivalent to the alcohol, and 0.5 per cent. phenol was added. Control tests with other diseases were constantly negative, and only the tests with proteus obtained from Paris and Vienna were positive.

Lean Diabetes. Barlow illustrates the microscopic findings in a woman of 32 who had been in the hospital for a year with progressive lean diabetes. The pancreas seemed normal, except for the conspicuous absence of islands of Langerhans, and the ovaries also seemed normal except for absence of follicles. No other abnormalities in the endocrine system or elsewhere could be detected.

The Medulla Oblongata. J. Añel—p. 100.
Acute Peritonitis. A. Alvarez—p. 107.

Hydatid Cyst Opening Into Biliary Passages.—Blanc Fortacin emphasizes that the clinical picture in these cases suggests infectious cholangitis with gallstones in the common bile duct only that the rapid course to an extremely intense maximum of the symptoms is not characteristic of gallstone mischief. Treatment must aim to clear out the bile duct as well as to evacuate the cyst. Attempts to drain the cyst into the gallbladder have proved disastrous, and this should be avoided. In his first case, the operation for evacuation of an abscess in the liver gave no relief although pus and bile had been removed. Then an incision close to the costal arch released quantities of pus and bile, but still no opening could be found in the liver. To reach the upper portion of the much enlarged liver he resected part of the costal cartilage, and here found the large suppurating hydatid cyst. It had perforated into the bile duct and this in turn had ruptured, with a consequent circumscript peritonitis.

The Medulla Oblongata.—Vidaló recapitulates in detail the normal and pathologic anatomy and physiology of the medulla according to the present state of our knowledge.

Persistence of the Gonococcus in the Urethra. V. Ribón—p. 6.
Fragility of Blood Corpuscles in Malaria. L. Netter—p. 52.
Relapsing Fever in Colombia. E. Robledo—p. 65.
Criminology in Colombia. A. R. Blanco and A. C. Merlano—p. 69.

Persistence of the Gonococcus in the Urethra.—Ribón warns of the danger of assuming that gonorrhea has been cured when the symptoms have subsided, as the gonococci may still lurk in the urethral glands and crevices. He describes how this can be detected and remedied by means of endoscopy, cauterization, copious permanganate irrigation, and massage with a stout catheter. He says that his remarks apply to both the male and female urethra.

Resistance of the Blood Corpuscles in Malaria.—Netter relates that in thirty-seven malaria patients the blood corpuscles displayed greater resisting powers during the malarial attacks than at other times. Quinin reinforces this augmented resistance and prolongs it temporarily. He queries whether it might not be possible to sustain and prolong this by other measures to combat hemolysis.

Spirochete Fever and Neo-Arsphenamin.—Robledo refers to relapsing fever as observed in Colombia, and emphasizes the prompt cure under neo-arsphenamin. He calls the parasite causing the disease the *Spirocheta franci* as Prof. R. Franco was the first to diagnose the disease and identify the parasite in Colombia and also the arthropod, *Ornithodoros chinche*, which is the usual transmitter of the disease. In one of the two cases reported, the patient had recently returned from New York. Rapid recovery followed intravenous injection of 0.3 gm. of neo-arsphenamin, part of which was lost, so the dose was repeated the same afternoon. In a second case a single injection of 0.45 gm. sufficed. He uses only 1 or 2 c.c. of water for the vehicle, and says that he has always had *maravillosos resultados* with this technic in a wide experience.

Bismuth Poisoning. Vaccarezza published in 1916 two cases of bismuth poisoning and he now adds several more

to the list. The bismuth suspension had been taken for roentgen examination. One man of 55 died after ingestion of 100 gm. of bismuth in the course of twenty-four hours. It had been fractioned in four doses, and death occurred three hours after the first symptoms; they developed eight hours after the roentgen examination. An infant a few months old, with megacolon, died in the same way after the bismuth meal. He cites four similar fatal cases from the literature; two were in infants. The toxic disturbances may occur when the bismuth is given either by the mouth or the rectum, but in most of the cases the bismuth had been partly arrested at some point in the digestive tract. The bismuth then, under the action of the bacterial flora, yields nitrites and their rapid absorption entails the cyanosis, the hemoglobinemia and the collapse. The poisoning from external use and tardy internal poisoning are the result of the transformation into a soluble albuminate, the absorption of which is followed by mouth and kidney lesions. Evacuation of the poison, venesection, heart stimulants and oxygen by inhalation and subcutaneous injection are the main reliance in treatment of the acute form of poisoning. He declares that bismuth subnitrate should never be used for any purpose in the digestive tract.

- *Jacksonian Epilepsy Following Influenza. E. F. Sanz. p. 249.
Influenza in Toledo District. C. Martín González.—p. 252.
Introduction to Study of Operative Surgery. J. G. Capdevila.—p. 256. Confin.

Postinfluenzal Jacksonian Epilepsy.—Sanz has already published cases of postinfluenzal aphasia, hemianopsia, and other nervous affections showing a focal lesion, evidently the work of the influenza poison. The frequency of these brain and meningeal complications and sequels seems to link influenza with the disease called lethargic encephalitis. In a case described a young man developed attacks of paresis in the left hand after influenza, with a tendency to abrupt contracture or tension of the muscles. At present this is only subjective, after a period of pronounced motor spasms. It seems to be a partial sensory epilepsy. Sanz has also encountered cases of hysterical monoplegia consecutive to influenza, and cites one published recently by Vivanco.

Pretuberculosis. B. Gil y Ortega.—p. 375. Confin.

Influenza and Typhus in Germany. Ferraz is the military delegate from Spain at the embassy at Berlin and this is his official report on influenza and typhus there. It is dated March 10, 1919, and states that the experience in Germany has confirmed the experiences elsewhere in this and previous epidemics of influenza in regard to the inability to check the spread of the disease on account of the impossibility of isolating the mild cases, the enormous diffusibility of the germ, and the appearance of thousands of cases at once. No attempt was made to close schools or theaters, etc., and declaration was not compulsory. The strict measures in this line that had been taken in some cantons of Switzerland had not seemed to check the spread of the epidemic, and Germany therefore refrained from anything of the kind. The bacteriologic findings differed widely and also the treatment. Köhler reported that he had found hot baths very useful, at 40° or 42° C. (104-107° F.). No mishaps were ever noted although the pulse usually rose and slight transient palpitations sometimes followed. Ferraz reported further that although there are twenty-four "lousoleums" in Berlin, to debauch the soldiers, yet typhus had got quite a foothold. In the two last two weeks in January there were 144 cases with 11 deaths and 502 cases with 28 deaths, but in the last week there had been only 18 cases reported, with 3 deaths.

- *Inoculation of Fowl Embryos with Human Cancer Tissue. K. Kato, Y. Sueyasu and H. Tsuji. p. 1.
Primary Cancer of the Appendix. K. Suzuki. p. 4.

Inoculation of Fowl Embryos with Human Cancer.—Kiyono, Sueyasu and Tsuji give an English summary of their long and illustrated report in Japanese of their inoculation of chicken, duck and geese embryos with human cancer cells. The cells from 64 cancer cases developed tumors in 12 of the embryos but in 3 of the cases the growth was not very pronounced. The 21 sarcoma implants gave 5 positive and 2 weakly positive responses; the 33 carcinoma implants 2 positive and one weakly positive; the 4 fibroma implants gave one positive result, and the one perithelioma elicited a weakly positive result. The outcome, the location of the human tumors and other details are shown in a table. When the tumor implants took root and grew, this occurred very slowly. The character of the tumor cells changed very little in some of the cases and in the others not at all.

- Pathologic Anatomy of Tuberculosis in the Dutch Indies. A. E. Sison. p. 1.
*Folklore about Tuberculosis in the Netherlands Indies. C. D. B. Langen.—p. 25.

Folklore about Tuberculosis in the Netherlands Indies.—De Langen sent a questionnaire to native physicians and health officers throughout the islands and to other persons whose occupation brings them in touch with sick natives. The replies emphasize that pulmonary tuberculosis is not encountered in children. It is supposed to be hereditary, and much interesting folklore is connected with it. A number of native remedies are described, and de Langen comments on the fact that so many of the formulas contain lime. In the mosques the water used to rinse the mouth for the prescribed ablutions is spit back into the basin and used over and over again in this way on Fridays when hundreds and hundreds visit the mosques.

Hospitalstidende, Copenhagen

April 23, 1919, 62, No. 17

- *Meningococcus Meningitis. O. Thomsen and F. Wulff.—p. 513. Confin.
in No. 15, p. 149.
*Examination and Treatment of Dangerous Probi Carriers. O. Thomsen and F. Wulff.—p. 519.
*Simplified Retention Catheter. H. B. Jørgensen.—p. 523.
*Psychography and Psychoplastics. J. Nielsen.—p. 529. Confin.

Meningococcus Meningitis.—Thomsen and Wulff comment on the recent Copenhagen epidemics of meningitis that they seem to prove that the close contact in military barracks is responsible for an exaltation of the virulence of the meningococci. No other assumption will explain the fact that of the 500 new recruits from all parts of the country, taken on the training ship "Eyen" March 26, 1917, ten developed within a week the most malignant form of petechial meningitis without contact with cases of meningitis. A chart is given showing the distribution of the 72 military and 114 civilian cases of meningitis during the 50 years in that district. The malignant petechial meningitis occurred in 59 of the military and in 58 civilians, but in the civilian cases contact with the military child almost invariably has been demonstrated. Under no other conditions is there such close living together of large numbers as in military barracks and possibly in mines, and we can assume that a certain number of the men are meningococci carriers. Others get the meningococci from them, and in some meningococci carriageal affection develops. They are then adapting themselves to this condition become more virulent by repeated, rapid transmission until they are able to induce the petechial type of the disease. These are admitted to civilians, but the meningococci are gradually losing their virulence until finally they are innocuous.

so slightly virulent that they are harmless for all except the least resistant, weakly infants in particular.

Thomsen and Wulff thus reject the idea of a special strain of meningococci as being responsible for the petechial type of meningitis. They argue that the virulence is not a constant property, but waxes and wanes. The meningococci linger usually long in the nasopharynx of convalescents from petechial meningitis, rebellious to all measures. In conclusion they say that the differential diagnosis in fulminating meningitis is often difficult; even cultivation from the blood may fail, and is almost sure to fail when not done until after death. But there is one finding that distinguishes meningococcus sepsis from other forms of sepsis, namely, the great accumulation of gram-negative cocci in the endothelial cells of the vessels in the skin of a petechial lesion. The cocci are found also in the lumen of these vessels. The skin should be examined for this as soon as possible after death, and fixation should be done with a weak solution of formaldehyd.

Treatment of Dangerous Carriers.—Thomsen and Wulff give an illustration of the arrangement at the State Serum Institute both for obtaining smears from the throat and for treating the throat of diphtheria, scarlet fever and other dangerous germ carriers. The aim is not only to protect the physician against infection from the subject's coughing, etc., but also to prevent accumulation of germs in the room. Two holes for the physician's arms are cut in a plate glass screen which is fitted into a window on the ground floor. The subject sits on a seat outside, in the open air, and the physician stands inside the room. A glass slide covers each hole when not in use; raising one closes the other, and both close automatically as the arms are withdrawn, so the carrier cannot talk through the holes. The screen does not prevent conversation. The spatula, etc., used on the subject are dropped into a pail on the ground outside before the arms are drawn in. A light is arranged above the window to throw a bright light into the throat. The illustrations show the carrier in cap and overcoat seated on the chair outside the window, his head held at the proper distance and position by an attendant standing behind.

Improved Retention Catheter.—Bisgaard comments on the drawbacks of ordinary retention catheters, and commends a device of his own which has answered its purpose admirably in several years of experience. It is merely an ordinary Nelaton catheter flexible enough to have the last fourth of its length bent to form a ring. He cuts a small opening, *b*, between the third and last fourth, sloping the top of the opening but keeping the lower edge perpendicular to the axis of the catheter, as it is thus stronger. Another opening, *c*, is cut in the opposite side, that is, on the same side as the original opening at the tip of the catheter but closer to the opening *b*, allowing about 2 cm. between them. With a needle, a silk, aluminum bronze or other smooth thread is then passed into the catheter and out through the extreme tip, a knot in the thread holding it firm at the tip. The threaded needle is then passed into the opening *b* and drawn out at the end of the catheter below. It is introduced like any catheter, but when the thread is pulled and fastened, the outer fourth bends into a circle, this circle holding the catheter firmly in place in the bladder. By untying the thread from the outer end of the catheter, the tip straightens out, and it can be withdrawn like an ordinary catheter. A knot near the outer end of the thread appears in sight when the ring is complete, and the end of the thread is then wound around the projecting end of the catheter. A small metal cylinder inside the catheter to strengthen it at its weakest point, namely, the opening *b* where the thread passes out and returns to the catheter, might prove useful but is not necessary for moderate use. Even in the worst, if the ring

should become incrustated and break off, it could be withdrawn by pulling on the thread, as the sides of the ring would be squeezed together as it enters the urethra.

Pyelography.—Nordentoft reviews at great length the advantages and disadvantages of pyelography and pyeloplasties, as encountered in his clinical experience and recorded in the literature. His final conclusion is that nothing is so instructive as pyelography in certain cases, especially with hydronephrosis, but that it should be used only with reserve and extreme caution. It is to be hoped, he says, that it may be possible yet to find some harmless contrast substance, and he warns that the procedure should never be applied to both kidneys at once.

Ugeskrift for Læger, Copenhagen

May 1, 1919, 81, No. 18

*Pseudohermaphroditism. K. Lehmann.—p. 751.

*Adjustable Capillary Pipet. P. Bogason.—p. 757.

Hereditary Pseudohermaphroditism.—Lehmann investigated conditions in the family of a female pseudohermaphrodite infant that had died from cachexia. A cousin of the mother was a male pseudohermaphrodite, and one of the infant's brothers had presented hypospadias and cryptorchidism, and it had also succumbed to cachexia at about the fifth week of life. Similar investigation of the familial antecedents in a case of pseudohermaphroditism recently published by Fibiger, revealed likewise malformation of the external genitals in three of the other six children. Two normal girls are living, but the boys all died in infancy. In both families all the children seemed to be strong and well developed at birth, except for the genital anomalies, but the children with the latter all wasted away and died in a few weeks without known cause. There was no enteritis. The early mortality is a striking feature of these cases; in Neugebauer's compilation of 1,250 cases of pseudohermaphroditism, 51 were less than a month old and 50 per cent. of these had died, as also 33 per cent. of the 93 other children under 10 years of age. The complete atrophy of the thymus in the infants whose cases are reported in detail suggests that the abnormal condition of the external genitals is accompanied by abnormal conditions in the endocrine system. This would explain the high and early mortality in such children. It suggests also that treatment with thymus might tide the children past the dangerous point or years. Corby reported the case of a pseudohermaphrodite of 15, a cretin, with polydactylia, and another child (dead) was also a pseudohermaphrodite. The parents were cousins, and most of their twelve children had died early. Lehmann discusses the application of the mendelian laws in these cases.

Improved Pipet.—The middle of the rubber bulb on the capillary pipet is squeezed flat with a small metal device. By turning the thumb-screw in this, the lumen of the bulb is opened, and it is possible by this means to aspirate a fluid into the pipet precisely to the desired mark, instead of the usual haphazard methods.

*Uric Acid in Urine in Health. A. Faber and E. Gottlieb.—p. 787.

Uric Acid in the Urine in Health.—Faber and Gottlieb have been conducting research to determine the indications for restriction to a milk-vegetable diet with joint disease or metabolic disturbances of any kind. One way to determine this is to give purins in a test meal and examine the amount in the urine. The previous experiments in this line to date have not been conclusive as they were made on patients with various diseases. The research here described was with twelve normal persons, and the tables given show thus the normal standard for comparison. Their diet was mixed, but with only 0.02 to 0.09 gm. nitrogen daily. The test meal consisted of 200 gm. sweetbreads, and the output of uric acid in the urine for three days afterward is charted for the different cases. The findings showed a proportional relation between the individual's weight and the capacity for eliminating uric acid, the two standing in inverse proportion, the larger the weight the less the output. Before the test meal, the output of uric acid varied in the different subjects from day to day by 3 to 37 per cent.

RELATION OF INTERNISTS TO MILITARY MEDICINE*

WALTER L. BIERRING, M.D.

DES MOINES, IOWA

It has been a traditional custom in the medical departments of the Army and Navy to regard the medical officers as surgeons, the director of each department being referred to as the Surgeon-General. There is but one instance in the history of the medical corps of the Army in which reference is made to a different title, the occasion being the appointment of Dr. William Brown as physician general of the middle department. Dr. Brown served from 1775 to 1780.

In the field of preventive medicine, bacteriology and sanitation, the federal medical services have a brilliant record of achievement, and many epochal contributions to scientific medicine have been made by officers of the several medical corps.

During the Civil War, Surgeon-General Hammond, well known as a physiologist and neurologist, and founder of the Army Medical Museum, created special hospitals for cardiac, pulmonary and neural diseases, at one of which Da Costa first described the condition of irritable heart in soldiers. In the Spanish-American War no distinction was made of a medical division in either base or field hospitals.

It was not until the entrance of this country into the world war that internists became more intimately related to military medicine, and it is one of my purposes in this paper to record briefly the part taken by medical reserve officers, recognized as internists, and particularly by members of this section.

INTERNAL MEDICINE IN THE WAR

At the time when war was declared on Germany in April, 1917, there were twenty-nine Red Cross base hospitals ready for service, having been organized from the Medical Reserve Corps under the direction of Col. Jefferson R. Kean, M. C., U. S. Army. This number was rapidly increased until within a very short time fifty Army Red Cross hospitals were assigned for duty overseas. These base hospitals were largely representative of medical college faculty or hospital staff organizations in civil life. A medical service was an organic part of each, being in charge of a chief and usually two assistants, all well known internists. Later about ninety-four evacuation, field and mobile hospitals were organized, composed of a proportionately smaller personnel, each of which included a medical service as a part of the respective hospital.

Early in the organization of the office of the Surgeon-General of the Army, the importance of tuberculosis and cardiovascular disorders was recognized, particularly in the operation of the selective service regulations, as well as special examination of officers and men at the various military training camps.

A division of internal medicine was created under which the subdivisions for tuberculosis and cardiovascular and gastro-intestinal diseases were included. The efficient organization of this new division was due in a large measure to the experience and foresight of the first chief, Col. Theodore C. Janeway; and his untimely death in the line of duty is one of the tragic incidents of this war. The high standards set by Colonel Janeway were ably maintained by his successor, Col. W. T. Longcope, until his assignment to foreign service, when he was succeeded by Col. Lewis A. Conner, who served until the close of the war.

As the large base hospitals were established in connection with the National Army and National Guard cantonments throughout the country in 1917, the selection of chiefs and assistant personnel for the respective medical services involved a responsibility of the highest degree, and it must have been a distinct comfort to all concerned with the health and welfare of the new army to recognize the character and standing of the internists assigned to the different stations. In a number of instances the chiefs of medical services later became the commanding officers of the Army hospitals to which they had been originally assigned.

It was the evident policy of the department to retain the regular medical corps officers in charge only long enough to permit the medical reserve officers the opportunity to become familiar with the military organization, after which the responsibility was promptly transferred to them.

VALUABLE EXPERIENCES

The readiness with which the medical reserve officer adapted himself to the new environment was remarkable. The internist in civil practice was considered fortunate if he had supervision of a service of from fifty to a hundred beds. To be suddenly called on to assume charge of a medical service in a military hospital comprising from 1,400 to 1,800 beds, and during the influenza epidemic as high a number as 4,700 beds, required the exposition of rare tact, judgment and organizing ability. The fact that it was so successfully accomplished reflects great credit on the Medical Reserve Corps.

The opportunities offered for observing large numbers of cases of a particular disease were unique. Attention need only be directed to some of the papers presented at the 1918 session and those offered for this meeting. Reports on from 600 to 800 cases of pneumonia, 350 cases of pericarditis, 280 instances of

* Chairman's address, read before the Section on Practice of Medicine at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

acute meningitis, 400 cases of arthritis, and 360 cases of epidemic parotitis, occurring in a single medical service indicate the unusual responsibilities entailed and represent a condition not likely ever to occur again.

It will no doubt be appreciated that the environment of the sick soldier as compared with the patient in civil life offered several new factors to be considered; nevertheless the accumulated records of careful observers will constitute a valuable addition to our knowledge of the particular diseases concerned.

It may be premature to indicate the gain to medical science through the experiences of military service; but even at this time it will be admitted that we have approached a little nearer to the control of respiratory infections; that attention has been more prominently directed to the extrameningeal manifestations of the meningococcus, and that a better understanding has been obtained of nephritis in the young, functional cardiac disorders, the effort syndrome and its importance as a problem in civil life, the result of inhaling poisonous gases, and the transmission and control of trench fever. The effect produced on diabetes among peoples affected principally by sugar restriction is one of the interesting revelations of the war period.

After the military hospital service was thoroughly organized, the medical officer lived under ideal conditions for the practice of medicine. Free from the embarrassment of professional competition and the financial cares of civil practice, he lived in congenial association with medical officers in charge of the surgical, roentgen ray and pathologic services, permitting daily conferences and a coordination of work contributing to the best in the diagnosis and the care of the sick.

As the medical officer, and particularly the internist, returns to civil life, it will be natural and very probable that he will wish to continue similar clinical associations at home, and thus gradually lead to a more general formation of groups of consulting specialists, a plan in keeping with the trend of modern medicine that promises much for professional development and the welfare of the public.

The purpose of group consultants in the American Expeditionary Forces will be considered at this session, and the advantages of this feature of the service more prominently presented.

The true function of the internist is exerted in the direction of higher attainments in diagnosis, and the degree to which military medicine was advanced in that respect may be a proper measure of the wisdom of establishing a special division of internal medicine.

MEDICAL TEACHING

In round numbers, about 150 military hospitals of the different types were established during this country's participation in the war. The fact that the department had great difficulty in finding a sufficient number of medical officers for the services in internal medicine is a commentary on the incompleteness of preparation among medical men for this special work.

In a study of the graduates of a leading medical school affecting the classes of 1915, 1916 and 1917 as to the preference expressed in the applications for commissions in the Reserve Corps, it was noted that a relatively small percentage chose the service in internal medicine; but on further investigation it was found that these usually represented the best students in the respective classes.

We are not specially concerned here with medical education as related to military conditions, recently so ably discussed by Munson and others,¹ except so far as the experiences in the services of internal medicine furnished the reason for this discussion.

The demonstrable use of examination methods, the proper interpretation of physical signs, and the ability to form diagnostic conclusions constituted the criteria of efficiency in this branch of the military service. It was in many instances the real index of the previous training of the medical officer.

Nevertheless it reflects great credit on the medical resources of this country that it was possible in one brief year to develop the School of Military Medicine at Fort Oglethorpe, where in October, 1918, 3,000 medical officers and 30,000 medical corps men were being trained.

That it was possible by short courses of intensive instruction to remedy some of the defects in medical training recognized in the general practitioner on admission to military service was probably due to the fine cooperative spirit and ideal conditions for teaching that prevailed in the military medical school. That it could so readily be done was indicative, at least, of a good fundamental education.

If the experience of medical teaching in the war has directed attention to an improvement in the scheme of education for the better practice of medicine, it will have offset in part the great sacrifices it has otherwise entailed.

INTERNISTS IN THE NAVY

It is fitting at this time to make reference to the internists afloat. At the beginning of the war the Medical Department of the Navy recognized the great need of internists, particularly in the large base hospitals in the naval training stations. Reserve officers were placed in charge of the different services of internal medicine, having supervision also of the clinical laboratory; and as rapidly as possible a similar plan was carried out on all ship hospitals and base hospitals overseas.

As the internists in the Naval Reserve are gradually being returned to civil life, Surgeon-General Braisted has endeavored to meet the occasion by requiring of medical officers of the Navy attendance at the Navy Medical School for a three months' course each in the branches of surgery, laboratory and clinical diagnosis, and the head specialties to determine fitness for special service, indicating that the new departure inaugurated during the war is to be continued.

The entire transport service was in charge of the Navy, and the completeness with which old vessels were transformed into hospital ships with every equipment for the care of sick soldiers and sailors testified to the initiative and organizing ability of the Navy Medical Corps. When the story is fully told of the devotion and sacrifice of medical officers in connection with influenza epidemics aboard ships, it will constitute one of the heroic chapters of the war.

DISTINGUISHED SERVICES

It is not possible at this time to recall the many examples of heroism displayed by the medical reserve officers; but there is a source of pride in directing attention to a few instances, and furthermore to the

1. Munson, E. L.: The Needs of Medical Education as Revealed by the War, *J. A. M. A.* 72:1050 (April 12) 1919. Vaughan, V. C.: Contributions of the Medical Department, *ibid.*, p. 1095. Foster, N. B.: Medical Education as Revealed by the War, *ibid.* 72:1840 (May 24) 1919.

manner in which the medical officer measured up to the demands of entirely new duties.

Reference has been made to the assignment of internists as commanding officers of cantonment base hospitals in this country, and evacuating hospitals in the American Expeditionary Forces, indicating that they had recognized administrative ability. The medical officers, among whom were several well-known internists who received the Croix de Guerre, form a large list.

It is quite impossible to estimate in any appreciative sense the service to the country of Colonel Billings in establishing the division for the rehabilitation of the disabled soldier and sailor.

In investing Brigadier-General Thayer with the Distinguished Service Medal, the citation read:

As chief consultant in medicine of the A. E. F. it was largely through his individual efforts that the treatment of the sick was so standardized, coordinated, and proficiently perfected as to result in a direct saving of many lives and a consequent conservation of man power and morale of these forces.

One of the contributors to the war unit program of this section applied for active service, April 6, 1917, and went to France with the Second Division. In civil life he is associated with one of the prominent medical clinics of the country. With practically no surgical training, his entire military service was concerned with the charge of stretcher bearers and dressing stations at the front.

In regard to Capt. M. C. Pincoffs, the Division Surgeon, Lieut.-Col. Richard Derby reports that:

His services have been of a high order of excellence. He possesses great initiative, and has performed every duty required of him with vigor and thoroughness. He has maintained excellent discipline and morale among his subordinates. He has time and again demonstrated his utter fearlessness and disregard of personal safety in the various engagements in which the Second Division has participated, as evidenced by his having been recommended for the Distinguished Service Cross, the Medal of Honor, and the Croix de Guerre.

As an example of versatility of talent I would like to refer to a member of the section who in civil life is chief of a department of medicine in a large university medical school, and was inducted into active service a few days after contributing a paper on pericarditis at the 1917 session in New York. During a military service of twenty-one months he probably did not make a single heart or lung examination because his activities were directed in an entirely different direction. He became the chief of the school for sanitary instruction at the Fort Riley medical officers' training camp, and when the military medical training was later concentrated at Fort Oglethorpe, he was assigned to a similar service there. He developed an open air school of military hygiene including every form of apparatus and equipment for demonstration, which permitted every student officer to gain a comprehensive knowledge of the subject in a short period of time. One of his distinct contributions was an incinerator capable of disposing of 10 tons of garbage with a minimum of expense, which has been adopted by the Medical Department of the Army. By reason of his training as a clinician, Colonel Williamson was able to direct the instruction in sanitary medicine, of particular value to the military service and of incalculable benefit to the thousands of medical officers that came under his charge and their future usefulness in civil practice.

When the medical history of this war is written, the record of the internist will indicate an important part in the efficient accomplishments of the several medical services during the great conflict.

Equitable Building.

THE EARLY ROENTGEN DIAGNOSIS OF ULCERATIVE TUBERCU- LOUS COLITIS

LAWRASON BROWN, M.D.

AND

HOMER L. SAMPSON

TRUDEAU, N. Y.

Some years ago, it occurred to us that the reason tuberculous enteritis was so generally fatal was the fact that it was impossible by any medical means to give the intestine sufficient functional rest to enable it to resist and possibly to recover from its tuberculous lesions. Archibald¹ has shown what may be accomplished by proper surgical measures in carefully selected cases. For these reasons it has seemed to us wise to emphasize certain data, not particularly new, but certainly very little known, which may suggest the presence of tuberculosis of the large intestine, and thus aid in its early diagnosis. We shall not attempt to discuss the treatment of this condition, but refer those who are interested to Archibald's former article and to his forthcoming monograph on this subject. It might be added, however, that for surgical interference to be of any help, the diagnosis must be made in many instances long before symptoms, now considered characteristic of the disease, make their appearance. We refer to chronic, persistent diarrhea and abdominal pain, tenderness and rigidity.

The reluctance of many gastro-intestinal specialists to make an early diagnosis of intestinal tuberculosis emphasizes the importance of the procedure we shall discuss. Recently a patient with moderately advanced pulmonary tuberculosis saw, on his way back to Saranac Lake, a prominent specialist, who stated to him and confirmed it in a letter to us, that "no evidence of intestinal tuberculosis was demonstrated" in the patient. The patient had also seen, about the same time, a pulmonary specialist, who had apparently overlooked his intestinal tuberculosis, and stated that his lungs should improve as soon as his indigestion was relieved. At that time the patient had all the symptoms characteristic of intestinal tuberculosis, and we had suspected intestinal tuberculosis eight months previously, owing to the presence of constipation and irregular fever, and had confirmed the diagnosis by roentgenologic study.

CLINICAL DIAGNOSIS

The position of intestinal tuberculosis in the minds of many specialists today is similar to that occupied by pulmonary tuberculosis fifteen or twenty years ago. At that time, many refused to make a diagnosis of pulmonary tuberculosis without finding tubercle bacilli in the sputum, and the struggle to overcome this reluctance was long and hard. At the beginning of this century the presence in a patient with advanced pulmonary tuberculosis of chronic diarrhea, of more or less pain, of tender points in the abdomen, and

¹ J. Archibald: Tr. Nat. Assn. for Study and Prevention of Tuberculosis, 12: 117, 1917.

nothing suggestive of an acute abdominal condition, led to the diagnosis of intestinal tuberculosis and a uniformly fatal prognosis. In a few instances, patients placed on treatment, for example, small doses of creosote and iodoform, lost their abdominal symptoms, which did not recur up to the time of death. Such

tubercle bacilli in the sputum had them in the stools as well. These observations were controlled by animal inoculation. Later Petroff developed a technique which enabled him as the first to cultivate tubercle bacilli from the stools, and in some instances in which they had not been previously discovered by staining methods.

Walsh,⁹ in 1909, from his clinical and necropsy studies at the Phipps Institute, came to these conclusions:

Diarrhea, abdominal pain, tenderness and rigidity mean very little or nothing in the diagnosis of intestinal tuberculosis. . . . The diagnosis of intestinal tuberculosis cannot be made with the slightest degree of certainty from our present known symptoms, and since the condition carries with it an unfavorable prognosis, in order to reassure the patient, the nurse and the physician himself, the diagnosis should not be made, so that the patient will have a better chance for hopeful treatment.

These observations, of course, threw great doubt on the early, and, in fact, on any diagnosis of intestinal tuberculosis, and made newer methods most desirable.

It seems hardly necessary to dwell on the frequency with which intestinal tuberculosis occurs in the late and terminal stages of pulmonary tuberculosis, in which involvement of the intestine ranks next to that of the lung. The necropsy figures show an incidence of intestinal tuberculosis varying from 60 to 80 per cent., and such frequency itself suggests that the complicating enteritis and colitis may have much to do with the fatal outcome. It is only a step to conclude that in some instances removal of the early

cases were regarded by conservative thinkers as probable mistakes in diagnosis.

At this time, the occurrence of tubercle bacilli in the stools was considered proof positive of the presence of intestinal tuberculosis. Lichtheim² in 1883 was the first, it may be recalled, to demonstrate tubercle bacilli in the stools, but said that they occurred only in patients with intestinal lesions and not in those who swallowed their sputum. Bodo,³ as early as 1891, examined the intestinal contents of patients who had died of pulmonary tuberculosis, and as he found tubercle bacilli when there was no tuberculous enteritis, he came to the conclusion that the presence of tubercle bacilli in the stools was no sure proof of tuberculosis in the intestine. We can, nevertheless, recall the amount of time which some of our confères spent in searching for tubercle bacilli in the feces in order to confirm a diagnosis of intestinal tuberculosis. Again, Rosenthal, Strasburger and Schmidt elaborated special techniques for the examination of the feces for tubercle bacilli. Some years later several observers, Philip and Porter,⁴ Laird and Kite,⁵ Petroff,⁶ Engleson,⁷ and Klose,⁸ made routine examinations of the stools of patients with pulmonary tuberculosis and arrived at the conclusion that from 75 to 95 per cent. of all patients with tu-

bercle bacilli in the sputum had them in the stools as well.

These observations were controlled by animal stages of pulmonary tuberculosis, in which involvement of the intestine ranks next to that of the lung. The necropsy figures show an incidence of intestinal tuberculosis varying from 60 to 80 per cent., and such frequency itself suggests that the complicating enteritis and colitis may have much to do with the fatal outcome. It is only a step to conclude that in some instances removal of the early

Fig. 3 (Case 7473).—Six hours, prone. Note pleural shadows, no barium shadows having reached the cecum. There are questionable faint traces of barium in the descending colon. Patient was referred for pulmonary tuberculosis, far advanced. Emaciation, persistent diarrhea and abdominal pain were the symptoms. Site of roentgen-ray lesion: diagnosis of tuberculous colitis (site not determined) made on three days at six hour examination, plus practically complete absence of barium shadows at twenty-four hours. Death occurred a few months after diagnosis of tuberculous colitis was made.

Fig. 4 (Case 7875).—Same case as Figure 3. Twenty-four hours, prone, marked hypermotility.

intestinal lesions might prolong life or even help to bring about recovery, for, while tuberculous intestinal ulcers may heal, such healing is, so far as we know, infrequent.

SYMPTOMS

We have stated that the clinical symptoms positive of intestinal ulceration often occur so late in the course of the disease that a speedy termination of the case can be confidently expected. On the other hand, extensive ulceration may be found at necropsy with no symptoms occurring during life. Such symptoms, then, may be of little value if remedial measures, especially of a surgical nature, are to be applied. We feel that when any patient, even in an incipient stage, begins to do poorly, and shows no increase of pulmonary symptoms or signs, or, what is even more significant, a lessening of signs and symptoms referable to the lungs, intestinal complications should be borne in mind. Further, if under these circumstances the patient exhibits extreme nervousness, constipation, slight dyspepsia, a feeling of fullness or discomfort in the abdomen after eating, in all probability accompanied by gas, so frequent in all patients undergoing treatment for pulmonary tuberculosis, or fails to gain weight under suitable conditions, the probability of intestinal complications is strengthened. These symptoms may be accompanied at times by a very slight and brief attack or by attacks of diarrhea, readily amenable to simple remedies. A slight, irregular rise of temperature may or may not be present.

As the disease progresses, the symptoms increase and depend on the location of the ulcers, the irritation of the nerves, the involvement of the peritoneum, and, of course, the effects of the ulceration on the intestinal contents (blood and pus).

In some instances, the patient complains that he does not feel well; his digestion is neither good nor bad, and he may have a slightly irregular temperature: often normal, but at times reaching 99.6 in the afternoon. In one such case, a slight thickening of the cecum and ascending colon was palpated, and at operation tuberculosis of the cecum and ascending colon was found and resected with good results.

In another case, with incipient pulmonary lesions, marked constipation was accompanied, at times, by persistent vomiting or regurgitation of food. A palpable cecum suggested intestinal tuberculosis, which was confirmed roentgenologically and by operation, with recovery as the result.

The point that we would like to emphasize at this time is that at the onset the symptoms of intestinal tuberculosis may be as slight and as indefinite as those of early pulmonary tuberculosis. In fact, the term "latent" might well be applied to many cases of intestinal tuberculosis, for, unless borne in mind and looked for, they escape detection.

PAIN

Severe pain is not an early symptom. At first, only slight discomfort is noticed. A little later, pain, just below the epigastrium, occurs at irregular intervals, often late in the morning or in the afternoon, and is at first transient, later, more often persisting, crampy or stabbing in character (suggesting gas), aggravated

by food, relieved by fasting and recurring every day to day (Archibald). Sharp and, later, lincinating pain may follow a glass of cold milk or even cold water.

DIARRHEA AND STOOLS

At the onset, the stools may be mushy and occur once or twice at night. Again, some have only one loose stool a day, accompanied at times by tenesmus or gripping. In some instances, the first manifestation is the disappearance of the previous constipation, and the patient remarks that his "bowels are better" because they move now without drugs. The diarrhea at first may be so transient and so easily remediable as to attract no attention. Later the attacks occur more frequently and are more severe. But diarrhea, even lasting for six to eight weeks in a patient with pulmonary tuberculosis, may be due to other causes than intestinal tuberculosis. Among those may be mentioned the irritation of swallowed sputum. Liebert says that diarrhea without ulceration occurs in from one tenth to one seventh of all cases coming to necropsy. As the disease advances farther, the diarrhea, no longer tem-

Fig. 5 (Case 5058).—Six hours, prone. Head of the barium column is seen in rectum. Note absence of barium shadows in the ascending colon. Patient was referred for pulmonary tuberculosis. There were definite periodic abdominal symptoms with pain. Site of roentgen-ray lesion: cecum and cecocolon. No operation was done. Twenty-four hour plate showed bowel entirely empty.

Fig. 6 (Case 5058).—Same case as Fig. no. 5. Enema plate, prone. Note filling defect in cecum and cecocolon and questioning in middle of transverse colon.

porary and alternating with marked constipation, becomes more stubborn and persistent.

It has long been felt that the discrepancy between symptoms in life, for example, diarrhea and the postmortem findings, are due to the location of the lesions. Diarrhea is rarely persistent until the disease has extended along the large intestine to the transverse colon, and even then constipation may be rather marked and persistent. If diarrhea is persistent, it is probable then that the disease has reached the transverse colon, though this may be involved without persistently loose bowels.

We would like to draw attention to the fact that the "constipation" complained of by some patients may be due to some abnormal abdominal sensation attributed by them to constipation, which, in reality, is not present. It is of interest to note that constipation and diarrhea may alternate to the end of life. The odor of the stools is usually fetid and penetrating, even suggesting, to an experienced observer, the presence of tuberculous enteritis. Intestinal hemorrhage is rare, but at times has led to a fatal termination. It is of slight

diagnostic value. Flatulence is very common, and "gas pains" are frequently described. The temperature may be at times more subnormal than usual. A slight rise is often present without any increase of physical signs or symptoms from the lungs. Some patients have marked mental depression and great and often unaccountable nervousness. Acute intestinal tuberculosis has been described with symptoms suggestive of acute endocarditis or sepsis. We have not encountered any such cases, and the acute cases seen by us are usually due to a tuberculous appendix. Intestinal tuberculosis is rare in acute tuberculosis. Several cases later shown to be intestinal tuberculosis have presented the blood picture of pernicious anemia. These conditions, however, are very unusual, and none occurred in the cases we are discussing.

jejunum, 28 per cent.; duodenum, 3.4 per cent.; ascending colon, 51.4 per cent.; descending colon, 21 per cent.; sigmoid, 13 per cent.; rectum, 14 per cent. (Fenwick and Dodwell).¹⁰ Other observers have also clearly shown that the jejunum is not spared. The symptoms of involvement of the appendix may dominate the situation. They may occur in attacks, usually mild. Tenderness may persist, and a mass, of course, may be palpable. The ileocecal region is most often involved. The symptoms are those described, but later the pain and tenderness are often localized to the region, and some thickening may be obtained. If there is no cecal thickening and the usual symptoms occur, with constipation, the small intestine may be involved. Archibald, from whose observations we have drawn some of these statements, believes that alternating con-

† Six hour examination.

‡ Twelve hour examination.

§ Eighteen hour examination.

ABDOMINAL EXAMINATION

In some instances, as we have said, abdominal examination may reveal some localized thickening; but this frequently may occur only late in the disease, and then is usually accompanied by localized tenderness. Ulceration of the cecum and colon may occur without thickening of the intestine. Tenderness more often occurs when the ileocecal region is involved; but tender points may occur elsewhere.

SITE OF THE LESION AND ITS DIAGNOSIS

The sites of the ulcerative lesions in 500 necropsies have been stated to be as follows: ileocecal region, 85 per cent. (confined to this region in about 10 per cent.);

stipation and diarrhea indicate an involvement of both the large and the small bowel.

LABORATORY DIAGNOSIS

Many laboratory tests have been devised, but none are pathognomonic of intestinal tuberculosis. The whole subject is in a state far from satisfactory.

Tubercle Bacilli.—Evidence has already been quoted to show that tubercle bacilli in the stools are of no value in the diagnosis of intestinal tuberculosis. They occur in from 90 to 98 per cent. of all patients with tubercle bacilli in the sputum, irrespective of the intestinal condition.

2. *Pus and Blood in Stools.*—The occurrence of either pus or blood in the stools points to intestinal ulceration, but both may be lacking and tuberculous intestinal ulcers may still be present. Blood should always be looked for after abstinence from meat for three days. Macroscopic blood is rare, though Kidd¹¹ and others have reported deaths from intestinal hemorrhage in intestinal tuberculosis.

3. *The Blood.*—The blood in rare instances may give a picture suggesting pernicious anemia, but usually the most characteristic finding is a leukocytosis, with a nearly normal relative count.

4. *Tuberculin.*—This may cause some increase of pain, but adds little in diagnosis.

5. *Urine.*—The urine may show a marked indican reaction.

It seems likely that either slight rise of temperature without increase of pulmonary symptoms, anorexia prolonged and marked, slight digestive disturbances, regurgitation or vomiting of food, nausea, slight abdominal discomfort or actual pain, constipation or slight diarrhea, or constipation alternating with diar-

may eventually become part of the routine work in many sanatoriums for pulmonary tuberculosis, and in every instance, no advanced case should be subjected to radical treatment until the intestinal tract is studied by this method.

ROENTGENOLOGIC EXAMINATION—PREVIOUS WORK

For some years, the medical profession has had at its beck and call a technic which discloses the variations in the motility and contour of the large intestine. It is rather curious that so few have made use of this procedure in the study of tuberculous colitis. So far as we are aware, the first to call attention in American literature to hypermotility of the cecum was Pirie, who, after carrying out work suggested by Archibald, wrote a paragraph in the article by Archibald already referred to. He states that in tuberculosis of the cecum he was never able to visualize the barium meal in the cecum and was greatly disappointed. By careful observations repeated at half hour intervals and continued for from four to twelve hours, he was able to show that the tuberculous cecum retained none of

Fig. 10 (Case 7521).—Six hours, prone. Note spastic, ragged appearance of cecum and cecocolon. There was hypermotility; the head of the column was in the rectum. The patient was referred for pulmonary tuberculosis. There was hyperacidity and occasional vomiting. Frequent regurgitation of food, marked constipation. Cecum palpable, possibly thickened. Site of roentgen-ray lesion, cecum and cecocolon, is indicated by lines. At operation, cecum and cecocolon were tuberculous. Operation was done with excision of diseased area. Confinement, one year after operation, apparently complete recovery.

Fig. 8 (Case 7213).—Six hours, prone. Note spastic, ragged appearance of ascending and first portion of transverse bowels. There was hypermotility; the head of the column was in the sigmoid. The patient was referred for pulmonary tuberculosis. There was occasional diarrhea; the stools were foul, and there was slight abdominal discomfort. Site of roentgen-ray lesions in ascending and probably in first portion of transverse colon are indicated by lines. At operation, the ascending and the first half of the transverse colon were tuberculous. Appendectomy was performed. Confinement twelve months after operation. There were no symptoms; the patient had gained 40 pounds. Twenty-four hour examination: bowel was entirely empty.

Fig. 9 (Case 7213).—Same case as Figure 8. Filling defect of the ascending colon and the ragged appearance of the first portion of the transverse colon (indicated by lines).

the barium meal which normally should have accumulated there. He based his conclusions on a study of about twelve of Archibald's twenty-seven cases.

It was quite natural that we should have undertaken the study of this method of early diagnosis,

as so many suspicious cases came under our observation. After our work was nearly completed, we discovered that in 1911 Stierlin¹² of Basel studied six such cases, in which later operation was done by Wilms. In these cases the absence of barium or bismuth shadows at certain times in certain sites, when normally they should have been present, suggested hypermotility. Stierlin diagnosed on this fact the presence of ulceration of the large bowel at the site which threw no shadow. In six such cases of tuberculous colitis and in one of chronic nontuberculous ulceration, Stierlin's diagnosis was confirmed at operation.

11. Kidd: *Allen's System of Medicine*, 5:216.

12. Stierlin: *Munchen. med. Wochenschr.*, 58:1231, 1911.

Several years ago, it occurred to us that the only treatment of tuberculous enteritis that promised much relief, or even suggested the possibility of cure, was surgical intervention, which led us eventually to discuss the subject with Archibald. For this reason, and because we have had an opportunity of seeing clinically and of studying roentgenographically some of the cases in which later operation was done by Archibald and by R. M. Brown, our interest in the subject has increased; especially is this true since we have been impressed with how little general medical practitioners and, for that matter, even specialists in tuberculosis, gastro-enterology, and roentgenology, know of the technic necessary to make a diagnosis of tuberculosis of the large intestine.

TECHNIC

The technic varies little from that used in most roentgen laboratories. The day before the examination the patient is requested to abstain from taking any laxative. At an appointed hour the next morning he is given a barium suspension on an empty stomach (formula: 1 tablespoonful of cocoa, 1 tablespoonful of

are absolutely necessary at all examinations. A day or two later, the patient, having taken an ounce of castor oil eighteen hours before, returns for a barium enema. The enema is administered by low gravity pressure, from 10 to 12 inches, and the injection is observed fluoroscopically. When the enema is seen to have reached the cecum or, as in many cases, has passed through the ileocecal valve, it is stopped and a plate is made in the prone position.

NORMAL MOTILITY

For convenience, we may say that the normal stomach empties itself in from three to six hours. The head of the barium meal reaches the ileocecal valve in from one to three hours. The ileum empties itself in from five to nine hours. The cecum is seen in from two to four hours after the ingestion of a meal. Six hours after the meal has been taken, the head of the column is seen at the hepatic flexure or the splenic flexure. Complete evacuation of the meal takes place in from thirty-six to forty-eight hours. The cecum remains well or partially filled from the fourth to the thirty-sixth hour.

Fig. 10 (Case 7521).—Six hours, prone. There is a spastic, ragged appearance of the cecum. The patient was referred for pulmonary tuberculosis. Leukocyte count was 16,000. There was a persistent, slight increase of temperature and alternating constipation and diarrhea. The site of the roentgen-ray lesion is in the cecum (indicated by lines). Operation was refused. Later there was marked increase of all abdominal symptoms. Twenty-four hour examination showed a marked hypermotility.

Fig. 11 (Case 7541).—Six hours, prone. Note absence of barium shadows at hepatic flexure. Some manifestation is seen in a series of plates taken on different days. Note the filling defect in cecum. There was hypermotility; the head of the column was in the sigmoid. The patient was referred for pulmonary tuberculosis. There was marked abdominal discomfort and severe "constipation." Surgical diagnosis was appendicitis. The site of the roentgen ray lesion was the hepatic flexure region (indicated by lines). At operation, tuberculosis of the hepatic flexure region was diagnosed. There was an adhesion across the cecum. Postoperative death resulted.

Fig. 12 (Case 7541).—Same case as Fig. 11. Twenty-four hours, prone. There was hypermotility. The bowel was virtually empty.

PATHOLOGIC HYPERMOTILITY

sugar, 1 tablespoonful of flour, 4 ounces of barium, and milk to make 16 ounces). The examination during the ingestion of the meal has often been omitted, on account of the patient's condition. However, it is not usually of any importance in this work. Six hours after taking the meal, the patient is examined fluoroscopically and roentgenographically. This examination is important, as at this hour, one should visualize the cecum and probably the ascending colon. An examination every half hour for the next hour or two may be necessary in order to catch the cecum partially or wholly filled. When possible, the patient is examined at the end of eighteen hours, but always at twenty-four hours. The eighteen hour examination may make the twenty-four hour examination unnecessary. Plates

occurred in from twenty to twenty-four hours, although it is not unusual, in a certain number of cases, to find a small amount of barium still in the rectum at the end of this interval. In many cases (usually the more positive), in six hours the head of the column could be seen in the sigmoid and rectum, while at the same time there was a small retention in the stomach. In view of the fact that the patients manifesting this hypermotility had not taken any cathartic for thirty-six hours prior to the examination, this rapid progress through the large bowel needed explanation. On closer observation, it was noticed in many of the cases that apparently the cecum or cecocolon was the seat of the

definite hypermotility. A typical illustration is Case 7875. The six hour examination gave no trace of barium beyond the ileocecal valve; the terminal ileum was well filled. The nine hour examination disclosed faint traces of barium in the cecum and a fair amount around the hepatic flexure. This case would seem to indicate that the cecum and cecocolon refused to retain the material delivered to it and passed it along about as rapidly as it was received. In none of the cases later proved at operation to be tuberculous were we able to visualize a well-filled cecum or cecocolon, with the usual smooth haustral sacculations. It appeared as though the ulcerated portion of the bowel was unable to retain the usual amount of barium; or, indeed, it seemed to be completely emptied. In many of the positive and probable cases there was noticed a definite ileac stasis¹³ at six hours with hypermotility in the cecum at subsequent examinations. Whether this apparent stasis was due to stricture, to spasm of the sphincter or to regurgitation, it is difficult to say. The last would seem to be very likely in many of the cases.

The question arose immediately: Could conditions other than ulceration of the cecum or of the ascending colon produce this rapid type of hypermotility with its peculiar attending features? A few control cases were examined after the administration of a cathartic (castor oil), and while there was an increase in rapidity of the passage of feces through the large bowel, the bowel did not present the same manifestations as are seen in those patients proved to have had tuberculous colitis. The former cases showed smooth haustration, and, while the contents moved along more rapidly than they did when not under the influence of the cathartic, a spastic or ragged contour was never visualized.

A few cases of acute or habitual diarrhea produced about the same manifestations as were observed in those in which cathartics were given. A study of an article by Jordan,¹⁴ in which he illustrates a number of cases of colitis and diarrhea, fails to reveal any indication of the hypermotility observed in tuberculous colitis. From a study of the prints in articles by Imboden¹⁵ and Spriggs,¹⁶ it seems possible to exclude definitely disease of the appendix as the cause of these manifestations. George and Leonard,¹⁷ in their book, apparently make no mention of such a picture as due to any other cause.

FILLING DEFECTS

The second, and probably the more important, manifestation observed was the spastic appearance of that portion of the bowel later proved to be involved, usually the cecum or cecocolon. The smooth haustral sacculations were absent and the bowel had a distinctly irregular and ragged appearance. In the positive cases the affected portions of the bowel were only partially filled. Under the fluoroscope, barium was seen to enter the diseased cecum; but a few minutes later it had passed on to the transverse colon. In some cases, while the abdomen was being palpated in the region of the ascending colon, the barium shadows were seen to move out of this portion of the bowel, even though no more barium had entered it, and vis a tergo could apparently be excluded. We have not been able to

reproduce this particular manifestation in patients having apparently no tuberculous colitis.

STUDY OF BARIUM ENEMAS

In many of the cases we were unable to administer barium enemas, owing to the weakness of the patients, who, however, had usually a positive diagnosis. With the administration of the enema, in some cases, the barium was seen to move slowly, as a smooth mass, until it reached the suspected portion of the bowel, where it stopped. It was usually necessary to increase the gravity pressure in order to fill, in part, this portion of the bowel, which at times showed here and there irregular, stringlike barium shadows, extending from the main column of barium into the portion of bowel we were attempting to fill. These manifestations suggested that the suspected portion of the bowel was in a state of spasm or collapse, and refused to receive the barium enema. By manipulation, however, it could usually be filled fairly well. In many cases, nevertheless, the filling was only temporary, for this portion of the bowel apparently developed a contraction or spasm, and the barium column was seen to move distally rather rapidly. In a few instances the ascending and transverse portions of the colon were emptied completely, producing a dilatation of the distal colon. The plates taken at this time which were considered to give positive evidence showed a definite filling defect in one or more portions of the bowel, usually the cecum or the cecocolon. So far, we have been unable to discover any condition, apart from intestinal ulceration, which produced this picture.

ANALYSIS OF RESULTS

In all, examinations were made in 110 cases. Three cases (2.7 per cent.) were negative for pulmonary tuberculosis; six cases (5.4 per cent.) presented only suspected pulmonary tuberculosis; eleven cases (10 per cent.) exhibited incipient pulmonary tuberculosis; in sixty-eight cases moderately advanced pulmonary tuberculosis was present, and in twenty-two cases pulmonary tuberculosis was far advanced.

Among the negative and suspected or doubtful pulmonary cases there was no roentgenologic evidence of tuberculous colitis. In these groups, however, there were a few cases which showed a mild hypermotility.

Of the eleven incipient pulmonary cases, seven were negative; one gave doubtful roentgen findings; three gave positive findings. Of the last three cases, one was proved at operation; one patient died of pulmonary and intestinal tuberculosis (?); one patient is alive, and has not been operated on.

Of the sixty-eight moderately advanced pulmonary cases, forty-four were negative; fifteen, doubtful, and nine, positive. Of these nine, four were proved at operation, and five patients were not operated on.

Of the twenty-two far advanced pulmonary cases, none were negative; five were doubtful. Of these five, three patients were not operated on, and two are dead. Seventeen were positive. Of these seventeen, nine were verified at operation; three ended with death; five patients were not operated on.

In many of the foregoing cases the operative findings tallied very closely with the diagnosis as to site and extent. The remainder, however, revealed more extensive ulceration than the plates or screen indicated. This can be readily explained by the fact that the barium remained such a short time in the diseased areas, particularly in the transverse and descending

13. We considered ileac stasis present if, at the six hour examination, the following was observed: stomach seven-eighths or completely empty, ileum well filled, no barium having reached the cecum.

14. *Ann. N. Y. Acad. Sci.*, 1918, 23, 194.

15. *Int. J. Surg.*, 1914, 1, 10, 1915, 2, 582, 1915.

16. *Surg. Gynecol.*, 1914, 1, 1919.

17. George and Leonard: *The Roentgen Diagnosis of Surgical Lesions of the Gastro-Intestinal Tract*, Boston, 1915.

colon, that it was mere guesswork when these portions of the bowel were under consideration to confirm or exclude tuberculous changes. Then again, the motility of this part of the bowel would in all probability have to be studied at different hours. The lack of haustration would depend largely on the character and quantity of the barium visualized.

Through the kindness of Drs. Robert M. Brown, R. C. Paterson, S. F. Blanchet and Charles C. Trembley, we have been enabled to study roentgenographically some of their cases. It is interesting to note that in this second set of similar cases, the results were identical with those mentioned above.

We have intentionally omitted from this article any mention of the diagnosis of tuberculosis of the small intestine. So far as we are aware, no one has yet been able to diagnose definitely tuberculosis of the small intestine. This should always be borne in mind in suggesting operative measures. We have at present the problem under study and hope to arrive at its solution.

A number of cases classified as doubtful, which presented, on clinical study, all the typical symptoms of intestinal tuberculosis, revealed at the roentgen examination a fairly marked tendency toward hypermotility, which was not sufficient, however, to enable us to regard it as a positive finding. Further, the cecum at the six hour examination (which usually extended over a period of at least fifteen to thirty minutes) never assumed its normal pouchlike appearance, but appeared more or less narrowed, or was distinctly incompletely filled, even though barium was seen distal to this site. The diameter of this portion of the bowel was apparently less than the diameter of the ascending and transverse portion. Normally, it may be recalled, the cecum is larger in diameter than any portion of the colon with the exception of the sigmoid and rectum. Furthermore, fluoroscopic examinations were necessary to confirm these data. The outline, while not typically ragged, did not reveal the smooth haustral sacculations normally seen. Finally, we would like to call attention to the fact that some of these cases were put in the doubtful group because we thought the plate might have been taken at a time when the characteristic appearance of the cecum was not present. Had we waited, a few minutes later we might have observed this portion of the bowel virtually empty. The enema plate, as a rule, with the possible exception that the cecal shadow was definitely narrower than the ascending colon, revealed no abnormalities. In a few of these cases operation has been done and they have been found tuberculous. Further, we would not like to assert that the absence of detectable hypermotility and filling defects absolutely excludes the possibility of tuberculous colitis. The presence of a beginning hypertrophic colonic tuberculosis may cause not only lack of emptying but even cecal retention at the end of twenty-four hours.

CONCLUSIONS

1. Tuberculous colitis can be diagnosed clinically with a considerable degree of certainty when the disease is far advanced.

2. On the other hand, in the early or latent stages, when remedial measures may prove of avail, the clinical picture may be of little aid in diagnosis.

3. In all stages, certain shadows cast by the terminal meal at the end of six, eighteen and twenty-four hours determine definitely the presence of colonic ulcerations, but the absence of such shadows does not absolutely exclude colonic ulcerations.

4. The roentgenologic picture shows hypermotility and spasm, or filling defects.

5. The presence of such a picture in a patient with pulmonary tuberculosis should lead to a definite diagnosis of colonic tuberculosis.

6. Tuberculous colitis occurs far more frequently than hitherto supposed, and must be excluded in all advanced cases and in any early case with any abdominal symptoms, before submitting the case to radical treatment.

7. No examination of a patient with pulmonary tuberculosis can be considered today complete without a roentgenologic study of the intestine.

THE EGGS OF DIPHYLLOBOTHRUM LATUM*

THOMAS BYRD MAGATH, Ph.D.
CHICAGO

Since most diagnoses of parasitic worms depend on the identification of the egg of that species in the excreta or the blood of the patient, it is very important that data should be available for the identification of the various eggs of the different species encountered in man. Ward,¹ in 1903, called attention to the importance of the eggs of human parasites, and in 1908 stated² that "the very existence of marked variation (in the egg size) in the records of a single form is presumptive evidence that in the absence of errors of observation, two or more species are confused under the single appellation." The importance of the size of the egg as a diagnostic feature has been emphasized by many writers, and Looss gives the size of the egg as a specific character in trematodes. All textbooks on laboratory diagnosis give dogmatic measurements for the parasitic eggs, and very little can be found on the subject of variation in them.

Foster³ has called attention to marked variations in the size of *Ascaris* eggs, both from man and from swine, while Cort⁴ noted in *Pneumonoecus similiplexus* from the kopard frog very definite variations in the size of the eggs. He stated that the variation within this species was greater than that between two species within the same genus. I have many times noted the great difference in the size of eggs of parasitic worms as seen in smears of feces, and have undertaken to investigate more carefully the degree of variation to be found in a single species.

* From the Department of Anatomy, University of Illinois, College of Medicine.

¹ Diphyllobothrium latum is perhaps more commonly known under the generic name of Dibothriocephalus, or Bothriocephalus. On the low of priority, however, the name used here is that of the host. An intermediate host of this parasite is to be found among gastropods, such as the perch and the pike.

Fig. 1.—Camera lucida drawing of an egg of *D. latum*, in which may be noted the hd at one pole and the thickened node of the shell at the other; $\times 680$.

The material for this study was kindly supplied by Dr. Charles S. Williamson of Chicago. A very large specimen of *Diphyllobothrium latum* was obtained from a patient, and from the macerated fresh proglottids were obtained a great number of eggs. One hundred of these were measured and the results recorded. None were measured which looked abnormal in any way, and only those which were oriented in the field with the polar axis parallel to the slide were used. All the eggs measured were well along in development, as was noted by the color of the shells and the segmentation of the yolk cells.

From a study of the measurements, it was found that the length of the eggs varied from 55 microns to 76 microns, while the average length was 63.94 microns. The transverse diameter varied from 41 to 56 microns, the average being 47.33 microns. The ratio between the width of the egg and its length varied from 1:1.19 to 1:1.56, with an average of 1:1.3775.

The longest eggs measured 76 by 49 and 76 by 52 microns, while the shortest egg was 55 by 46 microns. The egg having the longest transverse diameter was 67 by 56 microns, and the one with the least transverse diameter measured 60 by 41 microns. An egg of average length and average transverse diameter would have a ratio of diameter to length as 1:1.30.

It becomes evident from this study that the mere size of the egg in the case of this interesting cestode is not of a great deal of value in identifying the species with which the host is infected. This becomes all the

more evident when one recalls that the eggs of *Diphyllobothrium cordatum* are said to range from 75 to 80 by 50 microns, and those of *Diplogonophorus grandis* are given as being 63 by 48 to 50 microns. Even the eggs of trematodes and nematodes might be mistaken for these eggs if size alone is the criterion for distinction.

Fig. 3.—Photomicrograph of an egg of *D. latum*, $\times 400$, in which the characteristic features of the egg are shown.

within the range found to cover those of *D. latum*. The eggs of *Paragonimus* are but slightly larger, and some individual eggs are without doubt as small as the largest ones found in the cestode.

It is evident that if one is to make a positive diagnosis in the case of an infection with *Diphyllobothrium latum*, it will be necessary to have some characteristics which will identify the eggs found in the stools. Figures 1 and 3 illustrate the eggs of this species. It will be seen that within the shell there is an irregular mass of granular material which represents the rapidly segmenting yolk cells in which is surrounded the growing embryo. The shell is a light straw color, transparent and with a thin shell, which is less than a micron thick. Within this shell is a very thin membrane, and the yolk cells are within this membrane. The eggs are almost ellipsoidal in shape, but tend to be more pointed at one pole. This pole is fitted with a very small cap, which in Figure 1 is seen slightly opened. Later on the embryo makes its escape through this opening of the shell. At the opposite pole there is a minute thickening of the shell, which has apparently escaped the observation of previous workers, but which is constant and becomes more conspicuous as the eggs mature, just as in the case of the cap at the other end. With these characteristics, which are purely morphologic, one may make a very definite diagnosis of the presence of this worm, the egg lying within the range of size given above.

It is interesting to note the statements of previous writers on the subject of the eggs of *D. latum*. Thus Ward⁵ says:

Eggs oval, 0.05 to 0.07 long, 0.035 to 0.045 wide; they have a brown shell with a cover.

⁵ Ward, H. B.: The Parasitic Worms of Man and the Domestic Animals, Report for 1894, Neb. State Board Agr., p. 294, 1895.

Fig. 1.—Photomicrograph of a field of *D. latum* eggs, as seen under low power.

more evident when one recalls that the eggs of *Diphyllobothrium cordatum* are said to range from 75 to 80 by 50 microns, and those of *Diplogonophorus grandis* are given as being 63 by 48 to 50 microns. Even the eggs of trematodes and nematodes might be mistaken for these eggs if size alone is the criterion for distinction.

Ward,¹ quoting from Schauinsland, says:

The eggs possess a thick brown shell, and a small lid, which becomes especially distinct at the close of development. They contain a large amount of yolk substance, and do not increase in size. As in all *Bothriocephalids* the development is carried out in the water and not in the maternal body, so that the inconspicuous egg cell is only rarely to be found in the mass of yolk cells which usually completely conceal it.

Ward⁶ further states that the eggs are from 68 to 70 by 45 microns in size.

Castellani and Chalmers⁷ state that:

The brown eggs are oval, 68 to 71 microns in length, and 45 microns in breadth, with an operculum.

Stephens⁸ gives the following data:

Eggs large, with brownish shells and small lids, 68 to 71 by 45 microns; the ovarian cell, which is already, as a rule, in process of segmentation, is surrounded by numerous large yolk cells.

Faught⁹ says:

The eggs are large with brownish shells and small lids. They measure 0.068 to 0.071 by 0.045 mm.

Todd¹⁰ maintains that:

The ova are characteristic. They measure about 45 to 70 microns, are brown in color, and are filled with small spherules. The shell is thin and has a small hinged lid at one end. As the eggs appear in the feces the lid is not easily seen, but it may be demonstrated by sufficient pressure upon the cover glass to force it open.

Wood¹¹ says:

The eggs measure 45 by 67-71 microns. They are of a brown color and occasionally a small cap or lid can be demonstrated at one end of the egg. The shell is thin and highly refractile. The germ cells are often segmented and surrounded by a number of large yolk cells.

Webster comments thus:

The ova are brownish in color, ellipsoidal in shape, 68 to 71 microns in length and 44 to 45 in transverse diameter, have a thin shell, and a lid which may be opened or closed. The contents of the ova are coarsely granular or mulberry-like.

From these accounts it can be seen that the previous statements concerning the size of the egg in *D. latum* have been misleading on the basis of the present study, and from other indications I am inclined to think that all of our common species of parasites of man and the lower animals will bear investigation along the line of the size of the eggs. It is hoped that others who have material available will undertake such a study on fresh material. The quickest way in which to measure eggs that I know of is to project a scale on a card from a stage micrometer by means of a camera lucida, and to draw the scale, subdividing the spaces to have divisions equal to 5 microns. A similar scale is projected over this scale and at right angles to the first lines. Then the eggs are projected on the scale on the card by the camera lucida and the measurements read off. For the present work a magnification of 700 diameters proved efficient.

CONCLUSIONS

1. There is great variation in the eggs of *Diphyllobothrium latum*.
2. The average length is 63.64 microns, the average transverse diameter 47.33 microns, and the average ratio between transverse diameter and length is 1:1.3775.
3. Because of the great variation in the size of the eggs it is not wise to make a definite diagnosis of the presence of this species entirely from measurements of the eggs, but to consider the morphology of the eggs as well. The cap on one pole and the small thickened nodule at the other clinch the diagnosis. A thorough search for proglottids should be made in the feces in suspected cases.

A METHOD FOR THE PREPARATION OF PROPHYLACTIC AND AUTOGENOUS LIPOVACCINES *

E. C. ROSENOW, M.D.

AND

A. E. OSTERBERG, B.S., CH.E.

ROCHESTER, MINN.

out in a preliminary report. Owing to the slow absorption and the fact that bacterial toxins are lipotropic, larger doses may be given with less local and constitutional reaction than when the bacteria are suspended in salt solution. The formation of antibodies should be more marked and the resulting immunity more enduring.

The chief difficulty encountered in the preparation of a lipovaccine arises from the fact that the bacteria must be dried, and all methods used thus far for drying produce a clumping of the bacteria. This makes it necessary to break up the masses formed in the drying process before a homogeneous mixture in oil can be made. The method as worked out at the Army Medical School⁴ consists essentially in drying the collected bacteria in Petri dishes at a relatively low temperature (53 C.), which inevitably causes them to clump in a firm, hard mass. They are then separated by prolonged grinding in bottles containing steel shot. This requires cumbersome and expensive apparatus and involves a number of steps in which contamination is prevented with difficulty. The method is obviously impracticable for the preparation of autogenous vaccines. The possibility that the prolonged grinding may render the bacterial substance more readily absorbable is also an apparent objection.

We have tried various procedures in order to simplify the methods used. In connection with some work in poliomyelitis it was noted that streptococci and pneumococci not only remained gram-positive but also retained specific immunologic characteristics for many months when suspended in 50 per cent. glycerol. The dehydrating power of pure glycerol is well known, and it was thought that this might be an effective agent in drying the bacteria and in preserving their antigenic properties. But glycerol and oil will not mix, even when emulsifying agents are used, and hence this method was found impracticable. Drying the bacteria with absolute alcohol and ether or with acetone and ether, in which the bacteria are less solidly packed than when dried by heat, was thought of, but the possibility of destroying the antigenic properties would not justify the slight advantage gained, since the grinding process would still be necessary. The method of drying the frozen bacteria in vacuo is difficult, requires special apparatus, and does not eliminate the grinding process. The method of drying serums and other liquids at a low temperature in vacuo, as used by Burrows and Cohn,⁵ and by Marmier,⁶ was suggested by Dr. E. C. Kendall. This was found to be effective in getting rid of the water in a closed system and undoubtedly in preserving antigenic properties,

but the grinding process was still found necessary. It occurred to us that if the water were removed by distillation in vacuo from a water-bacterial-oil emulsion, the oil would prevent the clumping of the bacteria and thus make the cumbersome, time-consuming, and otherwise objectionable grinding process unnecessary. With this as the underlying principle, a method has been developed for the preparation of varying quantities of lipovaccines.

METHOD EMPLOYED

The steps in the preparation of large quantities of oil vaccines may thus be subdivided:

1. The method for the preparation of the bacterial paste is identical with that used in the preparation of saline vaccine. The bacterial growth contained in glucose broth is centrifuged out, the continuous feed centrifuge being used.

2. The bacterial paste is removed from the centrifuge bowl under a hood by the use of a spatula, and is transferred to the proper sized, wide-mouth bottle.

Sufficient sterile water is added to give a very dense but homogeneous suspension, and the mixture is thoroughly shaken. One c.c. of water to each liter of broth-culture medium gives about the correct degree of concentration. The bacteria suspended in water are killed by thermal or chemical means. If heat is used, the bottle is immersed in a water bath and kept at a temperature of 60 C. for one-half hour, at the end of which time cultures are made. If a chemical method is to be used, sufficient cresol is added to the water suspension to make it a 2 per cent. cresol solution. The mixture is well shaken. After it has stood for twelve hours, cultures are made. In the case of *Staphylococcus aureus* and of other resistant bacteria, heat and cresol are used in combination. The suspension is heated for one-half hour at 60 C. in a 2 per cent. solution, and then allowed to stand for twelve hours or longer.⁷ When the cultures prove sterile, the dense water-bacterial suspension is transferred to a proper-sized, round-bottom flask. We use the heavy Pyrex flask and have found it very satisfactory. For the preparation of large amounts of vaccine, for instance using the growth from 200 to 300 liters of glucose broth averaging 2 millions of bacteria per cubic centimeter, we ordinarily use a 3-liter flask. For smaller amounts a two or a one liter flask may be substituted. It is desirable, however, to use one of fairly large capacity because of the increased amount of surface obtained for the subsequent removal of the water in vacuo.

3. For each liter of broth culture, 5 c.c. of sterile cottonseed oil, containing from 5 to 10 per cent. lanolin, are added to the water suspension. To facilitate boiling and to aid in breaking up any bacterial clumps which may form, about 100 gm. of solid glass beads (3 mm. in diameter) or steel shot, three-thirty seconds inch in diameter,⁸ are added, and the flask is placed in the oven, as shown in Figure 1. Glass beads obviate any oxidase reaction which, in the case of steel shot, may result in a darkening of the suspension. The oven is maintained at a temperature of from 60 to 65 C. The oven and baking machine, although convenient, are not essential.

4. Sterilization in cresol is more effective at 37 C. than at room or higher temperatures. Suspensions accidentally contaminated with *Bacillus subtilis* are rendered sterile when incubated at 37 C. for from twenty-four to forty-eight hours, while the control suspensions at the lower temperatures continue to show living bacteria.

Numerous large batches have been evaporated by immersing the flask in a water bath at 65 C., and shaking it by hand at intervals. The flask is connected by flexible pressure tubing (1) to the condensing bottles (2 and 3), the first bottle serving as a condensing reservoir, and the second containing unslaked lime or calcium chlorid, which acts as a further drying agent. The parts sterilized include the flask, Tube 1 and Bottle 2. Tube 4 connects with the vacuum pump. The Geryk type of pump is used to develop a vacuum of 1 mm. or less of mercury. The rate of shaking is controlled by the small sewing machine motor (5) and the rheostat (6). The length of the stroke is 4 inches. Good agitation is obtained by using eighty strokes per minute. The time necessary to drive off completely all the water depends, of course, on the total volume present. From four to six hours ordinarily suffice for quantities requiring the removal of 150 c.c. or so of water. This length of time is proportionately decreased as smaller volumes of water are used. Until the water is practically all removed, the temperature of the evaporating liquid is from 10 to 15 degrees lower than that of the oven. The distillation requires little or no attention, the apparatus running very smoothly. As the mixture becomes more anhydrous, the viscosity is increased, and the suspension appears as a very thick emulsion when the major portion of the water is removed. As the last portions of water are driven off, the bacterial mass becomes solvated, forming a thick, nearly clear homogeneous suspension. It is important that all of the water shall be removed. The end-point of the distillation may be determined by the almost complete clearing of the mixture and the absence of water condensation in the condensing tube. The vacuum pump is disconnected at the cotton plug in Tube 4. The sterile cotton plug between Bottles 2 and 3 prevents contamination by the rushing air. The contents are poured through a fine mesh screen into a stock bottle in order to remove any pieces of cork or clumps of bacteria that may not have been broken up. To prevent any material loss of suspension, the flask may be washed out with small quantities of sterile oil.

4. For use as a vaccine, 1 c.c. of the stock suspension is diluted so as to give a final concentration of 50 billions of bacteria per cubic centimeter. For example, in the procedure just described, 5 c.c. of cottonseed oil are added to the growth from each liter of broth culture, representing 2,000 billion bacteria. Thus the stock suspension contains 400 billions of bacteria per cubic centimeter. This is diluted eight times, giving a concentration of 50 billions of bacteria per cubic centimeter for use as a vaccine. We prefer to base our dosage on bacterial counts rather than on the basis of weight of the bacterial substance. The percentage or error in weighing the dried bacterial substance, containing a variable amount of the precipitate formed in glucose broth as the result of acid produced during bacterial growth, is comparable with the experimental error made in counting bacteria. Moreover, it is difficult to avoid contamination in weighing the dried bacterial substance. If, however, the weight of the dried bacterial substance is desired when large amounts are dealt with, it may readily be obtained by subtracting the weight of the oil used from the total weight of the oil-bacterial suspension as removed from the flask at the end of the distillation.

5. The cottonseed oil and lanolin are sterilized in the autoclave at 15 pounds pressure for thirty minutes, and then

removed while hot and placed in a hot air oven at 100° for an additional thirty minutes, or longer if one is dealing with larger quantities. The flask should be of the water-mouth type to facilitate the entrance of steam; they should fit well to the top and stopped with a cotton plug. The distillation, together with the removal of the oil from the apparatus while hot, reduces to a minimum the amount of water taken up. Heating in the air oven insures sterilization and removes what water has been taken up by the oil. Contrary to the general opinion with respect to the difficulties encountered in sterilizing oil, we have experienced no difficulty by using this method. Control tests, in which the oil was contaminated with dust containing highly resistant spores, were found sterile in every instance, after using the foregoing method of sterilization. Because of the absence of water, the need for a preservative in lipovaccines is less than in saline vaccines. Various preservatives, such as camphor and chlorbutanol, have been used. In this method the small amount of cresol present in the stock suspension is sufficient to prevent bacterial growth from accidental contamination.

6. In order to insure complete sterility of the final vaccine, rigorous sterility tests are made: (1) of the water suspension of the bacteria after the cresol and heat have been used; (2) of the cottonseed oil containing lanolin which is added to the water suspension; (3) of the stock suspension after distilling off the water, and (4) of the final oil suspension to be used as a vaccine. The cultures are made on blood agar in tall tubes of glucose bran broth and litmus milk. In addition the final product is injected into animals to insure sterility.

In order to thoroughly mix large quantities of the stock suspension with the oil for final use, the machine constructed for us by Mr. Little, is found convenient (Fig. 2). It consists of a vertical, one-eighth horse-power motor (Fig. 2, 1) fitted with a removable sleeve (2) which contains bearings for the shaft (3), to which are fastened two propeller blades (4). These are thrown out horizontally as the shaft revolves at a rapid rate (1,700 revolutions per minute). The sleeve and shaft slip off together; these are sterilized and introduced through the small hole in the rubber dam (5). The support (6) is adjustable and is held securely in place by the hooks (7). The bottle, which has a capacity of 5 gallons, is filled three-fourths full. Smaller bottles may be used as required. The revolving blades are placed so as to produce a vigorous downward and outward current; hence the agitation is violent and soon results in an even mixture.

COMMENT

This method has given perfectly even, homogeneous suspensions with various species of bacteria. Large quantities of the mixed vaccine used for prophylactic inoculation against influenza, containing type pneumococci, Group IV pneumococci, green-producing streptococci, hemolytic streptococci and staphylococci, have been prepared by mixing in the centrifugal bowl the bacteria grown separately, as well as by mixing the dried oil suspensions of the different strains. In addition, excellent lipovaccines have been made of typhoid-paratyphoid and dysentery bacilli, of influenza bacilli, colon bacilli, *Streptococcus dysenteriae* from enterocardiis, gonococci and meningococci. The antigenic and toxic properties, especially in varying the doses

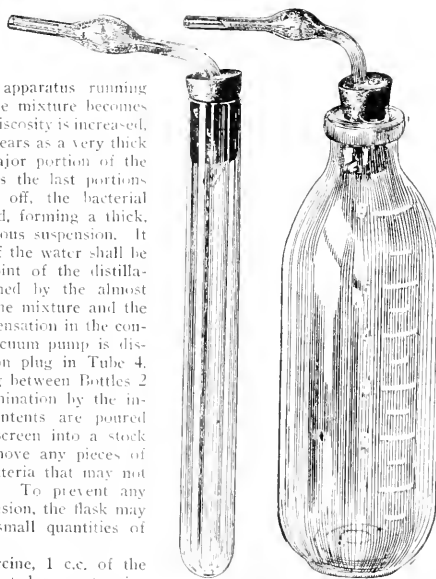

Fig. 3.—Flasks used for the vacuum distillation of water from water bacterial oil emulsion.

of the mixed vaccine for influenza, will be reported in detail later. It is sufficient to state here that as high as 90 billions of bacteria have been given to a few persons, with only slight constitutional and local reaction. A dose of 0.5 c.c. containing 25 billions of the dried bacteria in the oil given more than 500 persons during a recrudescence of influenza rarely produced more than a slight reaction. But after the use of this vaccine, as after the use of the saline vaccine, an occasional person reacted more severely and a sterile abscess formed. Antibody production—agglutinins—has been found pronounced following the injections of such dosage. It is therefore evident that the somewhat prolonged heating in the oil *in vacuo* when large quantities are prepared does not destroy the antigenic properties.

It is imperative that there shall be no living bacteria in the water suspension at the time the oil is added. Early in the work it was thought that heating during the distillation *in vacuo* would serve the double purpose of killing the bacteria and driving off the water. This was found not to be so. Many of the suspensions showed living streptococci and other bacteria after prolonged heating at temperatures from 60 to 75 C. Temperatures as high as 100 C. for a period of two hours failed to kill after the water had been removed.⁹ It is obvious that the mixture must be sterile at the time the oil is added. The heat used in the distillation does not alter materially the antigenic properties of the bacteria since it is not even sufficient to kill them. On the basis of this fact, moreover, there is good reason to believe that heating the water-bacterial-oil emulsion to the boiling point of water under atmospheric pressure will not destroy the antigenic properties of the bacteria. Should this be found to be the case the method might be simplified still further.

It is desirable in order to decrease the toxicity of the vaccine that the distillation shall be continued until the suspension has become cleared. This is well indicated in the following experiment: Two parallel series of persons—six in each series—were inoculated with equivalent doses of the mixed vaccine as used for prophylactic inoculation against influenza. One series received the incompletely dried, turbid suspension; the other the more completely dried and cleared suspension. Two persons in each series received each, respectively, 25 billions, 50 billions and 75 billions of bacteria subcutaneously. The results showed that the incompletely dried suspension was decidedly more toxic, producing more reaction, both constitutionally and locally, especially locally, than the completely dried suspension. There was no fever nor other evidence of constitutional reaction in any who received the latter. This decreased toxicity is apparently due to a detoxicating action of the oil or lanolin as they permeate the bacterial substance or to a delayed absorption or both.

The clearing that occurs as the oil permeates the dried bacteria is so striking as to suggest actual solution; but this is not what takes place, since the bacteria, on making a watery suspension from the oil, stain normally and are of sharp outline.

It has been found that the oil will not permeate bacteria dried in air in the usual way as completely as those dried *in vacuo* in the presence of oil. The toxicity of the former should, according to the foregoing experiment, be proportionately greater.

It may be suggested that desensitization against pollen or other protein substances may be greatly enhanced by the use of an oil instead of a saline suspension.

PREPARATION OF AUTOGENOUS LIPOVACCINES

The common 6-ounce nursing bottle shown in Figure 3 has been found useful for the preparation of autogenous lipovaccines. It serves admirably as a culture flask, centrifuge tube and vacuum flask. The bacteria are grown in tall columns of glucose broth (150 c.c. per bottle) for twenty-four hours, centrifugalized, the supernatant clear broth decanted, and the sediment suspended in 10 c.c. of a 1.5 per cent. solution of purified cresol in water or salt solution. This is thoroughly mixed and placed at 37 C. for from two to fifteen hours, when cultures are made. Streptococci and pneumococci are usually killed in from two to twenty-four hours. As soon as the suspension is found to be sterile it is centrifugalized; the supernatant fluid is decanted, and 6 c.c. of cottonseed oil containing 2 per cent. anhydrous lanolin and a number of sterile glass beads or steel shot are added. The mixture is emulsified by being shaken for a short time. The small amount of water from this water-bacterial-oil suspension is now removed by applying the vacuum and immersing the bottom of the bottle in water heated to 60 C. By means of vigorous shaking at intervals the removal of the water is hastened. The vacuum and the heat are applied until bubbling ceases and the mixture becomes clear. The time required depends on the completeness of the vacuum and the amount of water to be removed, but the clearing usually takes place in from twenty minutes to one hour. The ordinary bacteriologic test tube as shown in Figure 3 may be used for the preparation of still smaller amounts, but for most purposes the bottle is to be preferred. If larger amounts of bacteria are required, the water or salt solution suspensions of a number of bottles are placed in one, and a correspondingly larger amount of oil is added. By the use of Y tubes the water from a series of suspensions may be removed at one time.

If, for example, bacteria such as influenza bacilli, gonococci, and meningococci, which grow better on solid mediums, are to be used, the growth should be scraped together and washed off with salt solution so that the final suspension is roughly equivalent to that containing the bacteria from the broth culture. Sterilization and the further steps are carried out as above. In the case of the more resistant bacteria, such as staphylococci and paratyphoid bacilli, heating the cresolized suspension to 60 C. for one hour hastens the sterilization. The final bacterial content of the lipovaccine is calculated on the basis of counts made on the bacteria suspended in salt solution or on the basis of the total number of bacteria per cubic centimeter of broth culture. In the broth used in our laboratories, the amount of growth of pneumococci and streptococci is usually about 2 billions and the vaccine is made to contain approximately 50 billions of these organisms per cubic centimeter. The number of bacteria in the oil may be increased ten or twenty fold without inter-

⁹ This is exactly suggested at once the possibility that bacteria might live in oil for a long time when dried *in vacuo* in oil. Strains of many species of bacteria have been dried away and are being studied as to virility and antigenic properties. Both virility and specific immunologic properties of some have been retained for months. Also the present method for immunization against rabies might be greatly simplified if the dried virus (rabbit cord) were suspended in oil. The further results will be reported later.

fering materially with the evaporation of the water or with the even distribution of the bacteria.

The value of autogenous lipovaccines in the treatment of various diseases is now being studied. Striking cures have been noted following the administration of a single large dose of staphylococci (80 billions) in severe recurring furunculosis. Benefit has followed the administration of autogenous pneumococcus and staphylococcus lipovaccines in infections of the maxillary sinus. Judging by the slight constitutional reactions, even when huge doses are given, and the improvement in the few cases studied, it would seem that much good might come from the use of autogenous lipovaccines, especially in the treatment of chronic or recurring infections, when a prolonged immunization is indicated. Marked benefit, it would seem, might come from the use of autogenous lipovaccines in diseases due to focal infection, particularly if foci are removed and the vaccine is made to contain the specific micro-organisms as isolated from the focus.

THE NEWER METHODS OF CESAREAN SECTION

REPORT OF FORTY CASES *

JOSEPH B. DE LEE, M.D.
CHICAGO

The classic cesarean section has come to be one of the safest laparotomies, and at the same time one widely practiced. There is no question that it is too widely practiced, the trust in its general safety being great. This idea in regard to its general safety is the result of the publication by obstetric specialists of series of from fifty to 100 cases without mortality. I myself have had more than 100 successive classic cesarean sections without maternal death ascribable to the operation. Even the people have become imbued with the notion that cesarean section is entirely safe. Indeed, one woman was sent to me by a physician who told her the abdominal delivery was *the* method of childbirth of the future.

MORTALITY FROM CESAREAN SECTION

Accoucheurs of experience know that cesarean section is not so safe. They know that their good results are due to the careful selection of the patients submitted to the operation. They have observed numerous fatalities when proper strictness was not observed in deciding on the abdominal delivery. F. S. Newell said he knows that in several towns around Boston, the mortality (unpublished) from cesarean section has been frightful. He reports eight deaths in 100 cases at the Boston Lying-In Hospital up to 1909. Amand Routh, in 1910, found a general mortality for England of from 2.2 to 34 per cent., depending on the condition of the mother at the time of the operation. Cragin had 143 clean nontoxic cases with three deaths. Williams believes the general mortality will be 10 per cent., and only in the most ideal surroundings and, at the beginning of labor, will it be from 1 to 2 per cent.

In Chicago, deaths due to cesarean section not infrequently occur but are not put on record, and recently the newspapers of a certain county of the state pub-

lished a successful cesarean section as a wonderful achievement, the woman being the first to survive the operation in the county.

There is an unavoidable mortality to cesarean section. It increases: First, with the length of labor; one might say about 1 per cent. every two hours; second, with the number of vaginal examinations made, or operations attempted; third, with the rupture of the membranes; fourth, with the lack of skill of the operator. Furthermore, there are certain women who carry infection in the vagina—harmless there, but fatal if brought on to the peritoneum. There is no way of discovering it beforehand. Leopold of Dresden found gonorrhea in some of these cases.

MORBIDITY OF THE CLASSIC CESAREAN SECTION

In addition to the mortality, the classic cesarean section has a distinct morbidity. Just as the mortality has been gradually reduced by proper selection of the cases, by operating early, by refinement of operating-room technic, etc., so has the morbidity been reduced—but not in like proportion. A large proportion suffer from peritoneal shock. In fully 20 per cent. of the cases there is fever after operation. Uterine abscess occasionally follows, partial paralytic ileus and gastric dilatation not seldom occur, adhesions of omentum or intestine to the uterine or abdominal scar are the rule, and the danger of rupture of the uterine line of suture in subsequent labor is still a real one. The five main objections to the classic cesarean section are: the inherent mortality, the frequency of abdominal complications, adhesions, rupture of the scar in subsequent labor, and the necessity to restrict the operation to clean cases.

In infected, or possibly infected cases of obstructed labor, since pubiotomy is too dangerous, craniotomy is the only alternative; and it is to reduce the necessity of this horrible operation that the newer methods of cesarean section have been developed.

Since the objections enumerated always beset the classic cesarean section, and since the greatest dangers came from the fact that the peritoneum was opened, the old accoucheurs sought to avoid this necessity and tried to extract the child from beneath the peritoneum. The first suggestion came from Joerg in 1809, and Ritgen performed the operation in 1821. Physick of Philadelphia, in 1824, recommended this method to Dewees of Philadelphia, but I could not find that Dewees had performed it. Joerg had suggested that the incision be made in the flank, and that the peritoneum be dissected upward, in the manner preparatory to ligation of the internal iliac artery, the child then being extracted from the parturient canal. In 1870, T. Gaillard Thomas revived the operation which had been named "gastro-clytrotomy" by Baudeloque. Very few of these cases were successful, as we can readily understand. It was because of the lack of asepsis, and infection killed nearly all of the women.

ATTEMPTS TO IMPROVE THE CLASSIC CESAREAN SECTION

Attempts to improve the classic cesarean section, to make it adaptable to the neglected cases, failed until 1906, in which year Frank, of Bonn, disinterred the old extraperitoneal methods. He opened the abdomen just above the pubis, united the peritoneum of the uterus to the peritoneum of the abdominal wall, thus shutting off the general peritoneal cavity, and delivered the child through the almond-shaped space provided.

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, June, 1919.

Later Sellheim attempted to push the peritoneum upward from off the bladder, as was recommended by Physick in 1824, which thus freed the space over the cervix and lower uterine segment, through which he delivered the child.

Many operators, mostly continental, developed these ideas, and now there are about twenty different procedures.¹ All these methods of performing the operation depend on certain changes which occur during pregnancy and labor in the relations of the cervix and lower segment to the bladder and vesical peritoneum.

We know that during pregnancy the peritoneum over the lower uterine segment and bladder becomes very much softened and loosened from its base. It also hypertrophies under the stimulation of pregnancy. With the development of the lower uterine segment and cervix in the latter weeks of pregnancy and particularly in labor, the muscle of the cervix is drawn away, upward and outward, from the bladder attachments. The vesico-uterine culdesac is usually obliterated. The peritoneum is also drawn upward at the sides of the bladder in the neighborhood of the round ligaments. At the same time the mobility of the peritoneum on the subjacent structures becomes much

remitted. The general peritoneal cavity thus is temporarily removed from the field of operation, and infectious matters, such as meconium, liquor amnii and blood, are not permitted to spread over it. Some operators cut the line of temporary peritoneal sutures, and reunite the individual layers of peritoneum. Others do not do this, but sew the two layers together. Sellheim sews the uterine wall to the skin and leaves the wound open to drain, and calls such a delivery one through a utero-abdominal fistula. Among the transperitoneal cesarean sections, that invented by Krönig and modified by Gellhorn of St. Louis seems to possess most advantages, and is used in suspected cases.

Of the extraperitoneal methods, that of Latzko is the best. In Latzko's operation the incision is made either transversely or longitudinally, just above the pubis. The peritoneum is pulled out of the pelvis, the bladder is pushed off of the cervix to the right; and beneath the vesico-uterine fold which has been pushed up toward the navel, a bare space of cervix and lower uterine segment is provided, through which the child is delivered.

THE INDICATIONS

From the description given above it is evident that two new operations have been added to our armamentarium. Both have this in common—the lower or cervical zone of the uterus is opened for the delivery of the child, whereas, in the old, the classic operation, the corpus or fundus uteri is opened. We must hereafter speak, therefore, of cervical cesarean section, and corporeal, or classic, cesarean section. Since there are two methods of cervical section, and each one has its own indications and conditions, we have three distinct operations to consider when the question of abdominal delivery arises. It is not alone, "Shall we perform cesarean section in this case?" but, "Given the indication for abdominal delivery, what kind of section shall we perform?"

ABSOLUTE AND RELATIVE INDICATIONS FOR CESAREAN SECTION

The old teachers divided the indications for cesarean section into absolute and relative: The absolute indication existed when there was no possibility of delivering the child through the natural passages, the way being blocked by a contracted pelvis, a neoplasm, scar tissue, etc.; or the child being a mammoth. The relative indication existed, when, after carefully balancing all conditions, the accoucheur decided that the abdominal delivery offered the best chances for mother and child. It is therefore almost wholly subjective, and it left a wide field for the play of individual preference, for the influence of isolated experience, and for the clash of contending statistics. Moderately contracted pelvis, placenta praevia and ectropia are the main so-called relative indications. Before taking up the specific indications, let us study the comparative merits of the two contenders for favor, the corporeal and the cervical cesarean sections.

The objections to the classic cesarean section have been mentioned.

1. *The Mortality.*—I believe no one of experience will contest the statement that 2 per cent. of patients undergoing a clean nontoxic cesarean section die at present. Does the cervical cesarean section reduce this mortality? In reply to a questionnaire ten operators report 117 cases of transperitoneal and thirty-nine cases of extraperitoneal cesarean section, with

MORTALITY IN CESAREAN SECTIONS

Name	Extraperitoneal			Transperitoneal			Remarks
	No. of Operations	Deaths	Mother	No. of Operations	Deaths	Mother	
Thomson	6	1	1	27	0	0	
Brothman	1	0	0	4	0	0	
Davis	8	1	1	All infected cases
McPherson	10	2	2	All infected cases
McNeile	2	0	1	Both infected
Rutchie	1	0	0	
Chalfant	2	0	0	
Williams	4	0	0	
Polak and Beck	31	1	0	All suspicious
Kohlman	8	0	0	3	0	0	5 suspicious
De Lee, Stowe and Cornell	2	0	0	44	0	0	10 suspicious
	29	4	4	117	1	0	

increased. It is therefore possible, after incising this portion of the peritoneum, to push the bladder off of its cervical attachments with great ease, and to expose an area of the cervix and lower uterine segment large enough for the delivery of the child without encroaching on that portion of the peritoneum which is opened in the classic cesarean section. Of the twenty or more operations that have been invented, only two seem likely to obtain recognition.

THE TRANSPERITONEAL VERSUS THE EXTRA-PERITONEAL METHOD

All these methods may be divided into two classes: first the transperitoneal, or perperitoneal, and second, the extraperitoneal. In the transperitoneal operation, the abdomen is opened above the pubis, and the peritoneum over the cervix, near the bladder, is incised and loosened from its bed. By means of closely set continuous sutures, or by clamps, the parietal and visceral peritoneal layers are united. Some operators omit this part and protect the general peritoneal cavity by packing sponges around the uterus. In clean cases no more is necessary. The lower uterine segment and cervix are then incised, the child delivered, the placenta following; then the uterus is closed and the double layer of the peritoneum also

1. For literature compare Nicholson: *Surg., Gynec. & Obst.*, Feb., 1919, p. 148; and Kusner: *Zentralbl. f. Gynäk.*, No. 34, 1918.

the death of five mothers and four babies. Hirst, Brodhead, A. B. Davis, McPherson, McNeile, Ritchie, Chalfant, J. W. Williams, Polak and Beck, De Lee, Stowe and Cornell did these operations, and it should be noted that most of these women were either frankly infected, or suspected, at least unsuitable for the classic section. Reusch² completed a list of 595 operations which have been performed in Europe, with a mortality of less than 2 per cent., and, again, these were largely on patients who were already infected.

My assistants and I have operated in forty-six cases without fetal or maternal mortality. Theoretically and practically there are many reasons why this should be so. The incision is made in the lower part of the uterus, the cervix, well known to resist infection. The same may be said of the lower abdomen; it resists infection better than the upper; hence, the Fowler position. The uterine wound is at rest, lochia is not squeezed through it by the after-pains, and furthermore, should a leak in the cervical line of suture occur, the leakage is under the peritoneum, between the bladder and the cervix, where it could be easily reached in three ways: by the cervix; between the cervix and the bladder—a simple anterior colpotomy—or by opening the lower corner of the abdominal wound. Should infection wander along the line of suture (as it often does) in the corporeal section, it at once reaches the peritoneal cavity; in the cervical section it reaches a safer area—one more easily drained.

Another element of safety is the entire absence of any handling of the intestine. Often the intestine does not even come into view. Liquor amnii, vernix caseosa, meconium do not soil the peritoneum.

2. *Abdominal Complications.*—Comparative statistics on this point I have been unable to obtain; but the opinions of careful observers are worth something. The convalescence after the cervical cesarean section is, without question, smoother than after the classic section. Peritoneal shock, ilcus, gastric dilatation, I have not yet observed—for reasons above mentioned; tympany and postoperative pain are decidedly less, and one gets the impression that the woman has suffered only a minor operation, not the ordeal of the old cesarean section. This feeling of well being after the cervical operation is really remarkable. The puerpera is more comfortable than a patient after an interval appendectomy, the convalescence resembling that after normal labor. These observations are confirmed by the interns and nurses who can compare the two kinds of operations. Of my own thirty-one cases, there was suppuration in only one case, which is the more noteworthy since in nine of them there was a slight suspicion of infection.

3. *Adhesions.*—Regarding peritoneal adhesions, I cannot speak finally, having operated on only two patients for the second time. There were none in the one case, and in the other there was suppuration, so we expected them. Titus reports three cases (reoperations) without adhesions. Continental accoucheurs report them absent, and theoretically they should be. In most of my operations the intestine was not touched, and in many of them it did not come into view at all. Furthermore, the contents of the uterus, which many times are irritating if not actually infectious, do not soil the general peritoneal cavity, and finally the line of uterine suture of the finished operation is only about

2½ inches long, smooth and without catgut knots, and when the bladder fills, is covered by this viscus. In the true extraperitoneal method (Latzko) the peritoneal cavity is not opened at all, and in the absence of infection, adhesions, ileus, etc., will not occur. Adhesions are sometimes caused by seepage of lochia. This is impossible with the newer methods.

4. *Rupture of the Uterus in Subsequent Labor.*—I found only two cases of this on record, and, in both of these, part of the incision had been made in the body of the uterus. In my two cases of pregnancy after the cervical operation, the scar was not visible at the second cesarean. Continental writers claim this immunity from rupture as a specially strong point in favor of the low cervical method. Experience with vaginal cesarean section in which the incision is made in the same part of the uterus is confirmatory. The freedom from danger of subsequent rupture is easily understood. When the cut is made in the body of the uterus, the wound surfaces are not at rest during the healing process. With each after-pain, the sides of the wound grind on each other, and even in the absence of infection, are prone not to unite. When the cut is made in the cervix, all this is absent. The wound is at perfect rest.

5. *Expansion of the Field for Abdominal Delivery.*—Without doubt, the cervical cesarean section will in many cases obviate the necessity of craniotomy, and its greater safety will allow us to perform the abdominal delivery under circumstances in which previously we may have desisted; for example, in eclampsia, breech presentation, or prolapse of the cord. Best of all, we may give the parturient a thorough test of labor, lasting hours if need be, which is most unwise with the classic operation.

SPECIAL INDICATIONS FOR THE CLASSIC CESAREAN SECTION

In general, I must say that the more I do these newer operations, the better I like them, and now they are the first thought when the question of cesarean section arises. For doing the old, or classic, cesarean section, I have to have special indications, and these are, usually, the necessity for instant delivery, the desire to remove fibroids, placenta praevia, when a Porro operation is to follow, and in the case of an extremely pendulous abdomen. Experience may prove it possible to omit some of these exceptions.

The choice between extraperitoneal and transperitoneal methods is still undecided, but the majority of operators prefer the latter. The true extraperitoneal operation has the distinct advantage that it protects best against peritonitis—infection, if it occurs, being less dangerous in the connective tissue, and drainage being easily procured. Its disadvantages are that it is often hard to separate the peritoneum and the bladder from the uterus, the peritoneum often and the bladder occasionally tearing through. The uterine incision sometimes extends down into the base of the broad ligament where lie the large veins and ureter; also the delivery of the child is technically more difficult and its mortality slightly higher. For these reasons, and further, since the results for the mother are almost as good, the transperitoneal operation is most often selected.

Let us now consider briefly the most common indications for abdominal delivery. In the presence of insuperable mechanical disproportion, that is, the absolute indication for cesarean section, the older obstetri-

2. Reusch: *Zentrabl. f. Gynak.*, No. 40, 1917.

cians could only do, if discovered in time, a therapeutic abortion, or the classic cesarean section at term. If the dystocia was experienced only after infection was present or suspected, a Porro or complete uterine extirpation was demanded, if the life of the woman was not to be forfeited.

Nowadays we may proceed differently. Therapeutic abortion is absolutely contraindicated. At full term we have four courses to select from: the classic cesarean section, the classic cesarean section with the Porro modification, the transperitoneal cervical section, and the extraperitoneal section. In clean and in suspected cases I recommend the transperitoneal cervical section, and in frankly infected cases, the extraperitoneal section or the Porro cesarean section.

Of the indications comprised in the term "relative," nearly every obstetric complication we know has been advanced as a good reason for abdominal delivery.

In the treatment of labor in pelves that are not absolutely contracted, my plan has become more simplified in recent years. Unless the patient positively demands the induction of premature labor, I do not do it, but I allow the pregnancy to go to term. Just before labor begins I make a careful rectal and abdominal examination to determine whether or not there is any chance that the fetus will pass through the pelvis. If I decide it is highly improbable, I do the transperitoneal cesarean section as soon as labor is well under way. If there is reason to believe that the head will go through, I give the patient a real test of labor. If delivery is impossible, in primiparas, I do the transperitoneal section, in multiparas either this or pubiotomy, being guided by the individual conditions present. This statement holds also for cases in which infection is suspected. In frankly infected cases I still fear to perform an abdominal delivery, in spite of the wonderful results recorded by continental operators. If such is necessary I would recommend the extraperitoneal method with free drainage in young women, and uterine extirpation in old. Williams recommends the Porro operation to meet this emergency. It is just in these neglected cases that the extraperitoneal method is the easiest of performance. The prolonged action of the pains has drawn the lower uterine segment out, pulling the uterovesical fold of the peritoneum high up away from the bladder, thus giving a large area for incision and the extraction of the child. However, in frankly infected cases, craniotomy is still to be held in reserve, since the child is almost always doomed anyway. Küster is the only authority to contend that the operation will completely eliminate the necessity for craniotomy.

Eclampsia.—I will not discuss the question as to whether or not cesarean section has a place in the treatment of eclampsia. I am not yet ready to go back to the expectant and medicinal treatment of my student days, nor do I treat every case by instant delivery. If one desires a rapid, easy method of emptying the uterus, and one unattended by shock, the transperitoneal cesarean section may be selected. It may be performed under local anesthesia, just the delivery of the child being assisted by a little gas-oxygen anesthesia.

Placenta Praevia.—If cesarean section is done for this condition, I prefer the classic operation. In abruptio placentae, the transperitoneal is the method of choice, unless great speed of delivery is required to save the child. For neglected shoulder and breech

presentations, prolapse of the cord, and in the innumerable other obstetric complications, the new operation will, I am sure, find a restricted field of usefulness.

24 North Wabash Avenue.

ABSTRACT OF DISCUSSION

DR. JAMES W. MARKOE, New York: Never have we had a better paper or one more called for than this one on cesarean section. I have had nearly thirty years' experience doing this operation. The curse of cesarean section is that it is too easy and too dangerous. The method brought forward by Dr. De Lee is applicable in all those cases in which we previously did the classical operation. I have never done the extraperitoneal operation except in cases known to be septic. I have had one death. In some of the septic cases in which the peritoneum has been opened accidentally it is possible to strip the peritoneum up to the umbilicus; in other cases this is not done so easily. The possibility of this operation taking the place of the old classical operation almost entirely is great. It has difficulties; pulling the bladder to one side is much more difficult in some cases than in others, especially if the head is very large. The women I have operated on by the method described by Dr. De Lee have come to me with histories of from twenty-four to forty-eight hours of labor, with a pelvis in which there was no possibility of the head coming through; forceps had been applied, version tried and cultures showed the streptococcus, staphylococcus and colon bacillus present. One of these patients died. Suppuration occurred in a few cases, and there was destruction of tissue. Using the Carrel-Dakin method the wounds healed extremely rapidly, without complications. I delivered one of these women again by cesarean section recently. There was no sign of adhesions. Had I known that such would be the case I would have done a transperitoneal operation such as Dr. De Lee describes. That is the coming operation.

DR. JOHN OSBORN POLAK, Brooklyn: I am entirely in accord with practically everything Dr. De Lee said in regard to the transperitoneal operation. I have had no experience with the extraperitoneal operation since my student days. Since 1912 I have been doing the transperitoneal operation. For a few years I did the Kernig operation until recently when at the necropsy on a patient operated on by one of my staff we found what happens. We have had seven necropsies in the last twenty years in these cases and all have shown that the infection is not from the spill but from the extension of the infection from the uterus through the suture hole. The history bears out the necropsy findings. The peritonitis develops five and seven days afterward and the patient dies promptly as the result of an ascending peritonitis. In those instances in which we had been using the Kronig operation, in line with what Dr. De Lee said, we could always cover the incision with the flap. If this incision was made too far up on the uterus and it was not covered the leak came through. A suggestion made by my associate, Dr. Beck, was to make an upper flap of the upper part of the peritoneum. The upper and lower flaps were retracted by retractors, the uterus incised and the child's head delivered by any method indicated. One point in technic is to put the lower and upper sutures in before the rest of the sutures are placed in order to bring the wound out of the field and make suturing of the wound easier. After that is done the upper flap is brought down over the line of incision and tacked by one or two sutures distal to the median line. In the convalescence of these patients there is no gas distention, no elevation of temperature. In this operation we are subjecting the patient to slight risk and if there is infection, drainage is easy and we do not have a peritonitis in which one is absolutely hopeless.

DR. BERTHA VAN HOOSEN, Chicago: The principal advantage of his operation is the fact that it is so much more difficult than the classical operation that it will not be attempted too readily by the man who does only occasional surgery. Another advantage is that the placenta will not give the annoyance that it often does in the classical opera-

tion. We must, however, use the classical operation and I have made a little attempt to copy some of the advantages of this cervical operation in the technic for the corporal operation. Opening the abdomen in the usual way the body of the uterus completely fills and actually plugs up the incision. One of the things I have often noticed is that the operator uses great haste, and especially those who are inexperienced seem to think there is great haste in opening the uterus. But you may cut the peritoneum and the muscularis with great deliberation. The incision is first through the peritoneum, which retracts. There is practically no bleeding. With another incision the muscularis contracts and the uterus is delivered. Another incision is made rather deeply. Just as you approach the endometrium in some one place the blood will spurt up. At this place push in the finger and separate the mucosa from the membranes and with the knife on your finger open up the uterus. Now that the uterus is opened and the membranes are normally ruptured you can see the form of the child through the membranes and the bleeding has again on account of the tension stopped. For a few moments it is better to use a little haste. You can quickly incise the membrane and just as you do this your assistant puts her finger in the upper angle of the uterus and hooks it over so as to clamp the uterus to the abdominal wall so that the intestines will have no opportunity to be seen and the liquor amnii will have no opportunity to escape into the abdominal cavity. With the hand still clinging to the abdominal wall and hooking the uterus the placenta is removed and the suturing is now begun. Following the suggestion of Dr. Polak the first insertion is through the lower part of the muscularis which is followed by a suture through the top of the incision. The finger is removed and the two sutures are used to bring the uterus closely up to the abdominal wall. You can suture as you wish. As soon as the uterus is closed this lower suture by which the uterus was suspended is cut away, but the upper one is left in place until the peritoneum is closed down to the umbilicus or at a point where there is no tension on the uterus, and when there is no more tension it is cut. The uterus, now contracted, fills the abdominal incision and the peritoneum and abdominal wall can be closed in the usual way. The chief advantage of the method is that little blood is lost and that you have absolute control of the abdominal contents.

Dr. GUSTAV E. ZINKE, Cincinnati: During the last month I have performed two cesarean sections which illustrate the ease of the operation and its dangers. The first was a perfectly clean case in a secundipara. There was no complication except a placenta praevia, and for that reason I did the cesarean section. I made a high incision finishing the operation with the patient in bed in thirty minutes from the time of my abdominal incision. She recovered without the slightest symptom and went home at the end of two weeks with her baby in her arms. The second patient had a so-called justinior pelvis. She had passed through a very severe labor, the child being lost because of forceps delivery and version and there were a good many injuries to the soft parts of the pelvis. I put her to the test of labor, but it proved that the passenger was larger than the passage. At the end of the first stage I concluded to do a cesarean section. I delivered the child without difficulty. The woman began to vomit soon after the operation and her husband, a doctor, attributed it to the calomel she had received the day before, saying it always made her sick for a week. She kept on vomiting, yet there was no serious distention of the abdominal cavity. The vomiting grew worse daily. After forty-eight hours I came to the conclusion that probably this was the beginning of an ileus. Her husband insisted that the calomel was responsible. This threw me off the track for another day. On the third day there was fecal vomiting, and the picture was clear. I opened the abdomen five days after the cesarean section and found a knuckle of bowel adherent to the uterine wound. The patient went home three weeks after the cesarean section—two weeks after we reopened the abdomen. Ileus is the danger of cesarean section. One point which impressed me in Dr. De Lee's paper is that cervical cesarean section, the old

operation, is locked on with favor in cases in which sepsis is present. There is one mistake which practitioners are apt to make when they speak of sepsis in puerperal cases. We have two forms of sepsis, sapremic and streptococic. Streptococic or true septic infection is nearly always fatal, no matter what you do. In the sapremic variety the patients usually get well if they are treated properly.

Dr. JOSEPH B. DE LEE, Chicago: The first impression a man gets of this operation is usually bad. Do not stop at the first operation but do three or four. In the presence of a virulent streptococic infection I doubt whether any form of section is safe. Therefore, craniotomy would not be safe. A Porro operation or extirpation of the uterus might possibly increase the patient's chances. There is a big difference between the ordinary forms of infection which may under unfavorable conditions become dangerous and the rarer cases of streptococic infection. Dr. Van Hoesen pulls up the uterus against the abdominal wall to prevent the intestine getting in the way. This is not necessary. A corporal cesarean section is a corporal cesarean section, no matter how you do it. Dr. Zinke seemed rather proud that he got his patient back into bed in thirty minutes. I know a man who did a cesarean section in eighteen minutes. Whether we take eight, ten or twelve minutes longer to do a complete operation makes little difference so far as the patient is concerned but it does make a difference when you are hurried. You put in fewer stitches and tie knots carelessly, do some damage to the tissues and do not make good uterine sutures. I put in four layers of sutures and sometimes five.

END-RESULTS IN MORE THAN ONE HUNDRED OPERATIONS FOR UTERINE MYOMA

OPERATIVE VERSUS ROENTGEN-RAY TREATMENT*

ARTHUR STEIN, M.D.

Associate Gynecologist, Lenox Hill and Harlem Hospitals

NEW YORK

In this contribution I hope to show, on the basis of accumulating personal experience and a careful comparison of my results with those of others, that in the successful treatment of uterine myoma surgery still is and probably always will be the most efficient measure at our command. Many attractive and apparently plausible arguments are continuously advanced on behalf of roentgen-ray treatment of these tumors, and the time has come for a definite agreement on this question in the best interest of patients and physicians.

An exaggerated confidence in the benign character of uterine fibroids, not warranted by facts, has led many to accept the roentgen-ray treatment temporarily, relying on surgery in case of failure. The tendency of fibromyomatous tumors of the uterus to undergo sarcomatous degeneration, as well as many serious complications on the part of other pelvic organs, are too often overlooked in the prevailing tendency toward generalization of roentgen-ray treatment. This serious risk I have emphasized before¹ in an article in which I mentioned the case of a young girl in the early twenties. We contemplated radiation for a large uterine fibroid, but for certain reasons decided to operate, and on microscopic examination found the tumor to be a fibrosarcoma. It is of great interest to note this patient's subsequent history, reported by Dr.

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventeenth Annual Session of the American Medical Association, Atlantic City, June, 1919.

1. Stein, Arthur: The X-Ray Treatment of Uterine Myomata: A Warning Based on a Study of the Literature. *M. Rev.* 89:991 (June 3) 1916.

Vineberg at the meeting of the New York Obstetrical Society in January, 1919:

About two and a half years after the first operation she came to the Mount Sinai Hospital with the complaint of pains in the lower abdomen, and two masses were found behind the cervical stump. At operation both these masses were found to be retroperitoneal, a considerable distance from the cervical stump, and lying deep in the abdominal cavity. They were both removed, and were found, on microscopic examination, to consist of myomatous tissue showing sarcomatous elements.

Dr. Vineberg quite rightly emphasized the importance of this case, for we had here the recurrence, extraperitoneally, of a myosarcoma after its removal from the uterus, in contradistinction to the belief that a myoma of the uterus, with sarcomatous elements, is not truly a malignant growth and seldom or never recurs or gives rise to metastatic growth.

It is, of course, impossible to recognize incipient or even advanced malignant changes of a myoma within the uterus. Its benign character is taken by the radiologist entirely "on faith." As Tracy² puts it, he is indeed to be congratulated if he can in every case determine when malignancy is present, or when the tumor is undergoing degenerative changes.

DIFFICULTIES OF DIAGNOSIS

The unrecognizable degenerative changes present in these tumors, as well as the associated pathologic conditions in the adnexa, have very recently been emphasized by Le Roy Brown³ as contraindications to roentgen-ray treatment. The absence of malignant change can be reliably established only with the assistance of curettage, permitting exclusion of a concomitant carcinoma of the uterus.

As is well known, however, it is in many instances absolutely impossible to perform a probatory curettage of the uterus because of the fact that the uterine cavity is entirely obstructed by an intramural myoma. In these cases we are unable to determine by microscopic examination whether or not sarcomatous changes are present in the tumor or carcinoma of the body of the uterus exists. No gynecologist, no matter how skillful a diagnostician he may be, is safe from the danger of mistakes in these cases. Furthermore, old, hardened pus tubes lend themselves to confusion with uterine myoma. Even sarcoma of the ovary may be mistaken for a fibroid growth.

Two examples of mistaken diagnosis recently came to my attention, and in both instances the patients were examined by several well trained diagnosticians, who all agreed that each patient had a simple myomatous tumor. When the first was operated on, the hard, regular mass was found to be not a myoma but a very old and large pyosalpinx sac, firmly adherent to the normal sized uterus. The second patient was a woman aged about 45, with two large tumors on each side of the uterus. These tumors were hard and easily movable and were thought to be subserous myomas of the uterus, whereas, on operation, the uterus itself was found to be perfectly normal in size and shape, and the tumors were found to belong to the ovaries. Each tumor was found to be about the size of a man's fist

and nowhere adherent, and, on microscopic examination, both proved to be spindle-cell sarcomas.

The case of a fibroid tumor associated with adenocarcinoma of the uterus in a woman aged 54, reported by Dr. Vineberg at the November, 1918, meeting of the New York Obstetrical Society, is also of interest in this connection. There was absolutely no reason to suspect malignancy until the extirpated uterus was opened, and evidence of extensive adenocarcinoma of the endometrium was discovered, requiring a second operation.

The statement of Stern⁴ to the effect that all uncomplicated cases of uterine fibroids are amenable to roentgen-ray treatment is thus seen to be open to the very serious objection that about 50 per cent. of the cases are complicated, as I shall show in my own material, and that it is not possible at the present state of our knowledge to acquit a given uterine fibroid of all suspicion in this respect.

DANGERS OF DELAY

In view of the high percentage of associated malignant disease, Deaver⁵ distinctly challenges any form of treatment tending toward delay. Many degenerative changes were discovered at the time of operation in his series of cases; of the last 513 myomas, 111 showed hyaline degeneration; hemorrhagic, necrotic or calcareous changes, or a combination of these, were found in twenty-six others. Pus tubes were noted fourteen times. Eight uterine fibroids were associated with cancer. Sarcoma of the ovary was also represented. Several associated ovarian cysts, when operated on, already showed early malignant changes. The exposure of these patients to carcinoma or sarcoma through postponement of surgical intervention, aside from a possible deleterious influence of radiotherapy through stimulation of tumor cells, is too serious and far reaching to be condoned by the conscientious gynecologist.

In my article,¹ previously mentioned, I have warned against the possibility of starting proliferative changes of a degenerative character in those cell areas of a radiated myoma which are not destroyed by the roentgen rays. Undoubtedly, in the case of sarcomatous tumors of both ovaries just referred to, which was diagnosed as myoma, the sarcoma would have been stimulated by the roentgen rays with disastrous results. The enumeration of similar instructive cases could be indefinitely prolonged. Tracy⁶ pointed out some years ago, on the basis of solid arguments advanced against roentgen-ray treatment of uterine fibromyomas, that with few exceptions the only rational treatment is early surgical intervention, for a certain percentage of these tumors undergo various forms of degeneration which may positively be hastened by the application of the roentgen rays, and other myomas are complicated by malignant disease in the genital organs.

The corroborative observations of others have naturally served to confirm me in the very decided stand I have previously taken against the roentgen-ray treatment of uterine myomas, for nothing has been brought forward to cause a change of attitude on my part. I am still convinced of the superiority of surgery, and find my experience supported by that of prominent gynecologists and surgeons, both in this country and in Europe.

LIMITATIONS AND FAILURE OF RADIATION

The question of radiation versus surgery in uterine myoma was recently discussed by Cernezzi,⁷ in Italy, whose findings are much in conformity with my own. He pointed out that not a few gynecologists, and the great majority of general practitioners, adopt and recommend a passive attitude, with more or less reliance on the roentgen rays in patients at or near menopause, waiting for its favorable influence on the tumor. According to these Italian statistics, there is good reason to modify this optimism, for in no less than 68 per cent. of his patients who had been radiated elsewhere, the symptoms of the myoma reappeared or became aggravated, with the result that operation was requested by the patients themselves. These statistical figures are of great practical importance, as the artificial menopause induced by radiotherapy is often credited with the cure of uterine myoma. It is admittedly unwise to wait for the problematic benefits of the natural change of life in the presence of well marked symptoms, or of severe and repeated hemorrhage due to a myoma.

Le Roy Broun,⁸ in a review of the uterine myomas operated on at the Woman's Hospital in New York during 1918, comprising 262 cases, is led by the excellent end-result of surgery applied to a series of consecutive cases to raise the very urgent question whether this record can be equaled by roentgen rays applied for the purpose of absorbing or curing the myoma. The roentgen ray, in his judgment, should be used in myomas only for the purpose of controlling hemorrhage, and then only when the contents of the pelvis can be mapped out clearly.

The assertion that fibroid tumors disappear under the influence of radiation cannot be taken seriously, according to Deaver,⁹ whose findings entirely coincide with my own. Such patients still have their tumors, although the symptoms may have been relieved. He accepts the view of those who hold, like myself, that the roentgen ray has failed to demonstrate specific power over fibroid growths, and is capable of doing great harm through delay of the necessary radical treatment.

RESULTS OF OPERATION

The surgical treatment of uterine myoma is simple, efficient and safe. The patient wastes neither time nor money, and her expectations of rapid relief are not doomed to disappointment.

In my own experience, as covered by the clinical material of the last two years in the Harlem Hospital of New York, and the last twelve months in the Lenox Hill Hospital, as well as in private practice, the surgical treatment of uterine myoma in the form of myomectomy (twelve cases), supravaginal hysterectomy (eighty-nine cases), vaginal hysterectomy (one case), and total hysterectomy (eighteen cases), in all 120 cases, was attended by very favorable results and a low mortality.

Age of patients.—The youngest two patients were 23 years of age. Very massive doses of radioactive substances would have been required, involving a permanent loss of ovarian function. The oldest patient was a woman, aged 62, with large multiple fibroids which had undergone necrotic changes and partial calcification.

Complications of Uterine Myomas.—These were represented by a variety of findings. Needless to say, a simple diagnosis of myoma was rendered in the majority of the cases, not of accompanying pus tubes, for example, on account of the large size of the myomatous tumor.

COMPLICATIONS OF UTERINE MYOMA

	Number of Cases
Single or double pyosalpinx	26
Acute or subacute appendicitis of retrocecal, adherent appendix (not including chronic appendicitis)	18
Large ovarian cyst, single or double (including dermoid)	17
Ectopic pregnancy	1
Hydrosalpinx or hematosalpinx	12
Intra-abdominal adhesions	8
Gallstones	2

The associated complications of uterine myoma in my series of cases are given in the accompanying table. These complications occurred, single or combined, in sixty-one cases, or 50.8 per cent. This percentage is much higher than those reported by other observers, such as Tracy⁶ (33 per cent.); but it is easily understood when consideration is given to the type of material we get at Harlem Hospital (a city hospital) at which the most desperate and complicated cases are received. This also explains our comparatively high mortality. We had four deaths, or 3.3 per cent., three of which occurred at Harlem Hospital in very complicated cases.

Mortality.—The entire series of 120 cases included four deaths, or 3.3 per cent.

One occurred in private practice in a woman, aged 39, with a very large myoma, large left pus tube and large right-sided ovarian cyst with many old adhesions, who died very unexpectedly on the sixth day after the operation, from acute cardiac dilatation. Her heart had been normal up to that time.

Another fatal case was one of very large multiple fibroids, complicated by early pregnancy, in a woman, aged 28, who was stuporous after the operation (total hysterectomy) and died without regaining consciousness. The actual cause of death could not be ascertained, as a necropsy was not obtainable.

A woman, aged 40, with a large fibroid and complications in the form of left pyosalpinx and dense adhesions of intestine and omentum, succumbed to hypostatic pneumonia forty-two hours after the operation.

Embolism was responsible for the death of a patient, aged 37, who, on the twelfth day following the removal of a large fibroid complicated by double pyosalpinx, cystic ovaries and appendicitis, was suddenly attacked by pains in the chest and died three minutes later.

Convalescence.—In the case of a woman, aged 40, with a large intramural myoma and many firm adhesions due to former operations, recovery was delayed by postoperative, acute dilatation of the stomach; but this was successfully controlled. Postoperative bronchopneumonia occurred in two cases. Thrombophlebitis of the left femoral vein was noted in a woman, aged 33, after supravaginal hysterectomy for multiple fibroids, which were complicated by acute salpingo-oophoritis.

Retention of urine occurred after the performance of supravaginal hysterectomy in a case of giant, multiple myoma, complicated by dermoid cyst, in a woman, aged 34. Another patient, aged 50, with a large intramural myoma and subacute appendicitis, complained of backache and passed gravel and blood following the performance of myomectomy. In a case of a large,

7. Cernezzi, Aldo: *Riforma med.*, 34: 233 (March 23) 1918.

inflamed, soft fibroid complicated by unilateral pyosalpinx in a woman, aged 30, supravaginal hysterectomy was followed by a stump exudate, which was successfully treated by incision and drainage. Superficial cutaneous infection occurred in two instances after supravaginal hysterectomy for multiple fibroids complicated, respectively, by chronic, bilateral salpingo-oophoritis, and by adherent retrocecal abscess.

Microscopic Findings.—The tumors were plain and simple myomas in the great majority of the cases. No instance of sarcomatous degeneration occurred in this series; but this was purely accidental, for sarcoma was demonstrated in myomas shortly before and immediately following our series. Hyaline degeneration of uterine fibroids was repeatedly demonstrated, and minor changes of a hemorrhagic or necrotic type were exceedingly common.

It has been my good fortune of late to operate, in private practice, on several patients who had received quite extensive roentgen-ray treatment without having been cured by it.

One case of special interest was that of a woman, aged 34, who had been sent by a New York gynecologist to a roentgenologist with a diagnosis of uterine myoma. After receiving roentgen-ray treatment the hemorrhages stopped for a few months, only to return again with increased severity. When I saw the woman, she was very much exsanguinated, and examination revealed a uterine myoma about the size of a man's fist. She submitted to a supravaginal hysterectomy and, I am glad to say, is in excellent condition at the present time.

Another case was that of a woman, aged 40, who had previously undergone three laparotomies, one for appendicitis, one for double salpingitis, and the third for a cyst in the right ligament and right oophoritis. She had been seen by another gynecologist, who made a diagnosis of a large myoma of the uterus and advised roentgen-ray treatment. In this case, also, the hemorrhages disappeared for a short time only to return again, and when I saw the patient I made a diagnosis of a uterine myoma the size of a man's fist and advised a supravaginal amputation. This operation was performed under extraordinary difficulties because of the fact that, in consequence of the three former laparotomies, there were tremendous adhesions between the intestines themselves and between the uterus and intestines. Because of an acute dilatation of the stomach on the fourth day, the patient made a rather stormy convalescence, but is now in excellent health.

POSSIBLE CONSEQUENCES OF RADIATION

When those strong adhesions between the intestines themselves, and between the uterus and intestines, are found, it is wise to consider their bearing on roentgen-ray treatment. Fixed at one point by adhesions, the same portion of the intestine is continually exposed to the strong roentgen ray, risking destruction of the intestinal mucosa, which might in turn lead to intractable diarrhea.

In my previous contribution¹ to the subject, some space has been devoted to the occurrence of intestinal lesions as a sequel of radiation, and I have quoted a number of French investigators who produced intestinal lesions through roentgen-ray applications in animal experimentation.

In a comparison of the operative and radiotherapeutic treatment of uterine myoma, Case⁹ arrived at the conclusion that the ray treatment should not be used when time is a factor, and that it cannot be used with safety in rapidly growing tumors, in fibroids com-

plicating pregnancy or when serious disease exists in the tubes or ovaries. Mayo⁹ emphasized that this type of treatment in myomatous disease is destructive, non-operative, but not conservative. The function of the ovaries, tubes and uterus is lost in practically all cases in which uterine myomas completely disappear under this treatment. No radical treatment of myoma by roentgen rays is possible without sacrificing the ovaries, thereby exposing those patients below the climacteric age to physical and nervous changes of an undesirable kind.

At best, the radiated patient retains her tumor, although the symptoms may be relieved. My views are in thorough agreement with those of Deaver,² as quoted above, and other authorities such as Tracy,² Frank,¹⁰ Mayo⁹ and Case.⁹

The operation for fibroid tumor of the uterus, as pointed out by Deaver,² and confirmed in my own experience, is one of the most satisfactory in all surgery. The mortality in his last series of 750 operations was only 1.73 per cent. Tracy's report² of 100 consecutive operations for uterine fibromyoma records a primary operative mortality of 2 per cent., while mine is 3.3 per cent. for reasons given above.

According to the preceding statements, it is evident that I am still an adherent of operative procedures in the treatment of uterine myoma and do not advocate, in these cases, any form of roentgen-ray treatment except with those cases in which operative interference is contraindicated, such as chronic cardiac or nephritic cases, and in those instances my preference would be for radium.¹¹

CONCLUSION

I do not deem the roentgen-ray treatment of uterine myomas a safe procedure for the following reasons:

1. It is impossible to determine whether the growth to be dealt with is a benign or a malignant tumor.
2. My statistics show that about 50 per cent. of all myoma cases are complicated by pus tubes, hydrosalpinx or hematosalpinx, acute or subacute appendicitis, ectopic pregnancy, etc.
3. In young women who have not reached the menopause, the roentgen ray is almost certain to destroy the function of the ovaries, resulting in a premature menopause.
4. The continued application of the roentgen ray is apt to have a deleterious effect on the intestinal mucosa.
5. My experience has shown the surgical treatment to be the safest (with only 1 to 3.5 per cent. mortality), quickest, and most reliable method at our command.

48 East Seventy-fourth Street.

ABSTRACT OF DISCUSSION

DR. GEORGE E. PEAHNER, Philadelphia: It is quite natural that in an audience composed of surgeons and gynecologists who operate, and of whom only a few are familiar with the roentgen ray and radium results, the sentiment should be in favor of operation. I disapprove of the radical position taken by Dr. Stein. It is my practice to treat the patients referred to me by gynecologists, depending on their diagnosis. Patients coming to me without a diagnosis are

advised to go to a gynecologist for such diagnosis. The great objection to roentgen-ray treatment of fibroids of the uterus seems to be the danger of malignancy and the difficulty of diagnosing malignancy. The single case which the author presented in which recurrence followed operation is a good argument against his own procedure. I have treated 150 patients and not one developed malignancy since. If from 7 to 10 per cent. of all fibroids are malignant what has become of those which I have treated by the roentgen rays? Where are the ten to fifteen cases of carcinoma that should have developed in these cases? What has become of the 200 or more cases of malignancy that should have developed in the thousands which have been treated and reported by roentgenologists? They have not developed. I do not say that to give the idea that we should be careless in diagnosis, but let us not be too radical. Let us give the patients the advantage of the best treatment. If we allow the gynecologist to decide which cases shall be treated by radium or roentgen rays we shall be on safe ground. I can give that advice to every roentgenologist. Only two out of the 150 patients I have treated had to have operations later on account of complications. These two developed pelvic abscesses requiring incision and drainage through the vagina. These two at least had this complication at the beginning of treatment. In one woman who was very fat and in whom the doctor had diagnosed myocarditis, operation was contraindicated. The other patient had a marked anemia which forbade operation. Both were inoperable cases. I do not believe that we should go to the other extreme any more than that we should say that all cases ought to be treated by the roentgen ray. The tumors do disappear under roentgen-ray treatment.

Dr. J. RIDDLE GOFFE, New York: I am very glad that Dr. Stein has read this paper, for I think the whole tendency of the discussion was in favor of the roentgen-ray or radium treatment. The operative work has not been emphasized sufficiently. I recall when operations on fibroids were very disastrous. Many of us can recall when the fatality was more than 50 per cent. We must bear in mind that during the last few years operative results have improved. Dr. Le Roy Broun has given us a record of 262 cases of fibroid tumor operated on by twelve or fifteen different men during 1918 with a death rate of only 1.53 per cent. Analyzing the cause of death we find that there were complications which would undoubtedly have been very serious following the application of radium and they might have been quite as fatal. Therefore complications are a large factor in fibroid cases and can be relieved only by operative procedures. I am in favor of adhering to the operative procedure. The dangers and discomforts of the radium treatment have not been emphasized sufficiently. In contrast, the operative procedure is more simple.

Dr. JOSEPH B. DE LEE, Chicago: I would like to ask those who have used radium whether any woman in their practice has become pregnant after the radium treatment. In three cases in which I used radium to preserve the uterus with the view of rendering possible a pregnancy, I have not yet been able to report such an occurrence.

Dr. THOMAS S. CULLEN, Baltimore: I have listened with much interest to the discussion of Dr. Stein's paper particularly that in reference to the part played by the roentgen ray. One of the gentlemen has told us that there is malignancy in from 7 to 10 per cent. of the cases he has treated, and further, if I mistake not, that these patients have been sent to him by gynecologists. This percentage is far afield from what Dr. Kelly and I have obtained in a careful examination of nearly seventeen hundred cases. In about 1.3 per cent. we found carcinoma of the cervix, in 1.7 per cent. carcinoma of the body of the uterus and in 1.2 per cent. sarcoma developing in or associated with the myomas. Thus in about 4.2 per cent. we have found malignancy. In those cases where carcinoma of the cervix is present the gynecologist will, as a rule, hardly refer the patient to the roentgenologist, and in a certain percentage of the cases where adenocarcinoma of the body exists with the myoma the diagnosis will also be made. In these cases likewise the surgeon will deem

operation the wiser procedure. If we deduct the cases there will remain at the outside from 2 to 2.5 per cent. where the use of the roentgen ray or radium will be considered as a factor in the treatment. Radium and roentgen ray are without a doubt destined to play a large rôle in the treatment of fibroids. In a few years sufficient data will be available to enable us to crystallize our views on the subject. We will then be able to tell fairly accurately when to operate and when to advise roentgen ray or radium treatment.

Dr. HENRY SCHMITZ, Chicago: I had a patient, 42 years of age, who came to the clinic suffering with severe menorrhagia. Refusing any operative procedure, she was treated by radium. Nine months afterward she became pregnant and gave birth to a perfectly healthy child at full term. The infant is now five years of age and has no defect of development.

Dr. PETER B. SALATICI, New Orleans: I do not know anything about radium for fibroids, my experience being principally on the operative side. We lose very few cases by operation for fibroids and our results have been uniformly good. When we operate on a patient she generally convalesces well and that is the end of it. In many cases where radium is used, the patient is relieved partially for a time and then must go back and have the radium reapplied. I have seen two or three cases, one especially, with very disastrous results. In one case there seemed to be a friability of the tissues and the rectum was opened in separating adhesions. We had to drain and following this there was a fistula. I think radium should be limited to cases which are inoperable, when the heart is so bad that you do not care to take a chance or the patient is so anemic that you merely want to tide the patient over and operate later. I believe that syphilis plays some part in the causation of fibroids. Many cases of fibroids occur in young women and often in unmarried ones. Many married women who have fibroids are sterile. I find that a larger percentage of fibroids occur in the negro race than in the white. You find more syphilis in the negro for the same reason that you find keloids there, the cause of which we know very little about. The heart complications are frequent in fibroids. In 25 per cent. of heart cases in which you cannot get a positive history of infection you find either a positive or weakly positive Wassermann. I have had a Wassermann made in every case of fibroids in the negro and the reaction was positive. Not every negro woman, however, with a positive Wassermann has a fibroid, although the large majority having fibroids show a positive Wassermann. I merely mention this fact because we are all anxious to know the cause of fibroids.

Dr. LE ROY BROUN, New York: As to the sarcomatous changes in fibroids referred to by Dr. Clark, our experience in nine years in the Woman's Hospital gives us seven cases out of 1,760 consecutive cases in which we operated, a little less than four-tenths of 1 per cent. This is in keeping with what Dr. Clark has said and is rather opposed to the figures usually stated in the literature which give the percentage as 1.5 to 2 per cent.

Dr. C. N. COWDEN, Nashville: We all know what our results are in operations for fibroids. In radium treatment, however, tissue is left behind. What the future of that tissue is going to be when the patient undergoes retrograde change, say at 60 years of age, we do not know.

Dr. MILES F. PORTER, Fort Wayne, Ind.: I think it important to bear in mind that on the side of the question of operation we have some adequate and definite facts. On the other side, we have some very suggestive facts. Our attitude in regard to the application of the roentgen ray to fibroids should be what it is in regard to cancer. It occurs to me that there is no question but that the proper thing to do with a fibroid, other things being equal, is to take it out. Just as we do in cancer, we should call in a consultant and if there is any reason why operation should not be done the roentgen ray should be tried. In the meantime we must not forget that it seems to be proved very conclusively that mild doses of the roentgen ray increase the rapidity of growth of all sorts of malignant tissue. It has been proved rather

definitely by Kimura that mice carcinoma and sarcoma subjected to these mild degrees of radiation will grow with greater rapidity when grafted into other mice than they will when not exposed to this mild current; and, on the other hand, if they are exposed to rays of greater strength the growth is so inhibited that the grafts do not take at all. So that in the application of this method of treatment these facts should be borne in mind and the roentgenologist or radiologist should know pretty definitely whether he is dealing with a case which is malignant or one which is not malignant and the dosage should be applied in accordance with these facts. In the meantime, until we have something more definite we should go along the old lines. With a death rate of not more than 1 per cent. in uncomplicated cases, these patients should be subjected to operation unless there is some particular reason why they should be treated by roentgen ray or radium.

DR. ARTHUR STEIN, New York: Dr. Pfahler is to be congratulated on having such splendid results, but the question arises. Are these results obtained in all cases? As stated in my paper, I had three cases in which I operated after the roentgenologist had pronounced the patient cured because they had stopped bleeding for three or four months, only to bleed again much more than before. They are cured now after an operation. To my mind the whole question comes to this: We have all to improve on our diagnosis, so that we can rule out in each case with absolute certainty whether it is a simple myoma or one complicated by some other disease. If we can do that, then surely all the cases amenable to radium treatment ought to be treated by radium and not by roentgen ray.

ALTERNATING PERIODIC OVARIAN SWELLINGS *

EMIL RIES, M.D.

CHICAGO

From time to time certain abnormal conditions of the ovaries have been reported in isolated and unconnected observations, and it is my purpose in this article to endeavor to explain these and to link them up into a connected whole.

There are four types of cases which, I think, may be properly treated under this head. Descriptions of the first three types may be found in the literature, and I have encountered them in my own practice. These four types may be thus briefly described:

TYPE 1—THE VANISHING TUMOR

On examination of a patient, a cystic tumor, at the side of the uterus, of the size of a hen's egg, or larger, is found. The tumor suddenly breaks under the examining hand. The patient may have had some irregularity of menstruation and some pain. Pus tube or extra-uterine pregnancy may have been suspected and it is feared that rupture of the tumor may produce serious results. The patient is rushed to the operating room and an incision is made. A little serous fluid (sometimes blood-stained) is found in the abdomen. Both tubes are discovered to be normal. One ovary shows a ruptured cyst, the thin walls of which on examination prove to be those of a corpus luteum cyst, with more or less lutein layer in its walls.

TYPE 2—THE FALSE EXTRA-UTERINE PREGNANCY

A patient with more or less irregularity of menstruation, at times absolutely of the type found in extra-

uterine pregnancy, comes for observation and presents a soft cystic tumor at the side of the uterus. Other symptoms of pregnancy may be wanting or not decisive, one way or the other. The hemorrhage is most likely to suggest extra-uterine pregnancy and may be so protracted that it seems advisable to operate. Accordingly, the incision is made, but both tubes are found normal. Instead of an extra-uterine pregnancy a corpus luteum cyst in one or both ovaries is disclosed, usually with a thick lutein cell layer, often with chocolate-colored hemorrhagic contents in one or both ovaries. With the removal of the cyst or cysts all symptoms promptly cease. The pathologic examination shows a corpus luteum cyst or cysts.

TYPE 3—THE TUMOR WHICH DISTURBS THE PEACE OF THE COMMUNITY

The patient consults Dr. A in regard to certain pains in the abdomen, with or without much menstrual disturbance. The physician tells her she has an ovarian cyst on the right side and should have it operated on. After a few days, the patient consults Dr. B for confirmation of the diagnosis. He examines her and assures her that there is no tumor at all. The patient is now thoroughly disturbed and seeks the advice of a third physician, Dr. C. He examines her and tells her that she has an ovarian cyst; that it is not, however, on the right side, but on the left side. The amount of ill feeling created between practitioners themselves and their patients by such an occurrence may readily be imagined. In a case of this kind, which came under my observation three years ago, I advised the patient to have no operation for the time being and she is still alive and well. Further observation has proved that her case comes under Type 4, as I could suspect from her story. It was owing to my observations on Type 4 that I was able to treat the patient conservatively and my colleagues with sympathy who had made diagnoses differing from my own.

TYPE 4—ALTERNATING PERIODIC OVARIAN SWELLINGS

This type I have named alternating periodic swellings of the ovary. I gave my first description of it in 1913.¹

This group has now been studied in over a dozen cases since my attention was first directed to it in 1906. In three of the cases I have operated and have thus secured material for pathologic investigation. A number of cases have been observed in which the condition was present in a rudimentary way. In the case of the three patients operated on, and of some who were not operated on, my observations extended over several years: In Case 1 from 1906 until the operation in 1913; in Case 2 from 1910 until the operation in 1918, and in Case 3 from 1916 to the present time. Without this protracted observation in these cases and in a number of those not coming to operation, it would have been impossible to establish this clinical entity.

REPORT OF CASES

The first case of this kind to come under my observation was one in which the picture was presented in the most pronounced colors and may therefore deserve a more extended description:

CASE 1.—*History.*—When the patient first presented herself, she was 41 years old. She had had no previous sickness.

¹ *Festschrift* for Prof. Freund and Zischl f. Geburtsh. u. Gynäk.

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, June, 1919.

She had had a normal pregnancy, labor and puerperium at the age of 27. Her menstruation had always been regular, of three or four days' duration, with moderate loss of blood and without pain. In the summer of 1905, while on a European trip, she was taken ill with a severe inflammation in the abdomen. After several weeks of treatment she improved so far that she could return to America. A letter of the colleague who had treated her reported that she had considerable swelling of the right adnexa when she left him.

My first examination, Feb. 28, 1906, found the patient well nourished, with normal temperature, and all of her organs normal with the exception of the pelvic organs. The pelvic organs showed slight laceration of the perineum; moderate cystocele and rectocele; uterus large, hard, anteverted, movable; the right adnexa thick and adherent, barely sensitive; the left adnexa not enlarged, but not freely movable.

The conservative treatment that had been begun in Europe was continued, and the patient presented herself frequently for examination. In the course of several years the following observations were made:

March 15, 1906, the right adnexa were smaller. April 17, there was a feeling of heaviness and fullness in the right hypogastrium. The patient had just finished a copious menstruation of three days' duration. The right ovary was the size of a goose's egg. The left adnexa were adherent, but not enlarged. May 15, the patient reported that moderate menstruation had begun April 26 and had lasted three days. The right ovary was slightly thick. October 8, menstruation was reported regular. The findings were the same as last time. November 12, the right adnexa were quite small.

Jan. 28, 1907, the right adnexa were larger than a hen's egg. March 21, the condition was the same as last time. May 14, both adnexa were quite small. Menstruation was regular. June 17, the condition was the same as in May. November 8, there was pain in the back and in both hypogastria. Both ovaries were large, especially the left one, which was fully as large as a hen's egg. November 14, there was less pain. Both ovaries were small.

March 31, 1908, there was at times discomfort in the abdomen. This had been true more especially for a few days previously. Both adnexa were thick, and enlarged. Menstruation was regular. June 16, there were no symptoms. The adnexa were quite small. In October, 1908, menstruation was a few days early, and lasted three days. There was no pain. The right adnexa were larger than a hen's egg; the left adnexa were small. October 8, the right adnexa were the size of a hen's egg. October 26, there was no swelling at all. December 24, there was again pain in the abdomen. The right adnexa were the size of a hen's egg, and were slightly sensitive.

April 16, 1909, there had been pain in the abdomen for two days. There was a large swelling of the right adnexa, which appeared the size of a fist. There was a slight thickening on the left side.

In April, 1909, there was no swelling. May 12, the uterus was thick, and both adnexa were small. June 25, there was no swelling.

March 21, 1910, both adnexa were thick. Menstruation was regular. May 25, both adnexa were small. December 15, there was a right tumor the size of a fist, and a left swelling the size of a hen's egg. December 27, the left adnexa were quite small, and the right adnexa were the size of a hen's egg.

Jan. 3, 1911, there was no pain. The right adnexa were quite small, and the left adnexa were larger than a goose's egg. February 27, both adnexa were small. April 22, there was some drawing pain in the abdomen. The right ovary was somewhat large, and the left appendages were normal. May 24, the adnexa were small. July 3, the adnexa were small.

March 18, 1912, there was pain in the right hypogastrium. Menstruation was regular. The uterus was thick. On the right side was a distinctly cystic mass larger than a fist. The left adnexa were quite small. March 27, menstruation was reported as having occurred between March 22 and 25. There was a tumor on the right side of the same size as at the

last visit. April 5, the right ovary was quite small. April 23, menstruation was reported as having occurred between April 12 and 15. The right adnexa were quite small; also the left adnexa. May 28, the condition was the same as at the last visit. July 2, menstruation was reported as occurring between June 10 and 13. The left adnexa were enlarged; the right adnexa were small. December 27, the patient reported that for several weeks she had had pain in the left knee. The left adnexa showed a tumor the size of a fist. An examination of the knee revealed nothing of a pathological nature. Menstruation was reported as occurring, Dec. 7-10.

Jan. 2, 1913, there was a swelling on the right side the size of a fist. The pain in the knee was reported as at the last visit. January 10, menstruation was reported as having extended over three days. The pain in the knee was better. On the right side the adnexa were the size of a goose's egg; the left adnexa were only slightly enlarged. January 15, there was no swelling on the left side and only a small swelling on the right side.

Operation and Result.—After the patient had thus had thirteen right and seven left swellings, of which four had involved both sides simultaneously, and after the patient had frequently had considerable pain as a result of them, I proposed operative procedure.

The case came to operation, Jan. 20, 1913. The operative findings were as follows: There was a small left hydrosalpinx. The uterus was large. There was a fibroid the size of a walnut on the fundus. There was a small right hydrosalpinx in adhesions, and a small right ovary. There was a left ovarian tumor consisting of multiple cysts with clear contents and thin walls. There were adhesions of the sigmoid to the left hydrosalpinx, of the bladder to the anterior wall of the left uterus, and of the rectum to the posterior wall of the uterus.

The operation consisted in the removal of the ovaries and tubes and supravaginal amputation of the uterus.

Inspection of the appendix disclosed a thin cordlike structure connecting the normal point of insertion of the appendix with a small white calcareous nodule at the end of which an appendix of normal appearance was seen. The cordlike structure was 1 cm. long. The appendix was removed.

The pathologic examination of the removed organs disclosed two more fibroids in the uterus, and a thick mucosa. There were small cysts with serous contents and a partially yellow, partially white wall in the right ovary. In the left ovary there were cysts of the same kind.

Microscopically the cysts were corpus luteum cysts of various sizes and varying structure as to lutein contents. The fibroids were simple white fibroids. The tubes showed fibrous condition of the folds, and no other inflammatory condition. The part of the appendix which on inspection appeared normal showed on microscopic examination complete obliteration without a trace of mucosa or follicles.

The patient made a smooth recovery. The pain in the left knee disappeared quickly and had not returned on the last examination in March, 1913. At this time the pelvis was free from tumors.

If before the operation on this patient some justifiable doubt might have existed as to whether the swellings concerned the ovary or the tube, such doubt could be excluded with absolute certainty in Case 2:

CASE 2.—The tubes of the patient had been removed in 1910. At this time both ovaries were left behind and their inspection in the course of the operation had shown the left one absolutely normal and the right one somewhat thick and containing some small cysts with serous contents. Before this operation the patient had had two swellings, one on the left side in September, 1910, and one on the right side, Oct. 6, 1910. After the operation, up to 1917, this patient had at least seven swellings on the right and four on the left—twice on both sides simultaneously. In 1917, a fibroid developed which caused severe hemorrhages and was operated on in November, 1918. At this time both ovaries were removed with the fibroid. They were embedded in extensive adhesions and contained a number of cysts with bloody and serous

contents, which, on macroscopic and microscopic examination, proved to be corpus luteum cysts of various stages.

In Cases 1 and 2 the symptoms which accompanied the swelling were a feeling of fullness in the hypogastrium, a bearing down sensation, backache, and in the first case, at one time, pain extending into the knee of the affected side.

In Case 3 the symptoms were somewhat more severe and showed the connection of this type of case with Type 2 as described above.

CASE 3.—This patient had a prolapse operation in September, 1916, after the method I have described elsewhere.¹ The patient made a good recovery.

Oct. 12, 1918, she reported that she had been flowing for a month without pain, that she felt nauseated, and that her breasts felt full. A week previously she had passed something like a membrane. The examination revealed a firm tumor to the right and behind the uterus. She was put under observation and reported, November 24, her last menstruation as occurring from November 1 to 8. The tumor was unchanged. As she had been sterilized in her prolapse operation and as I had never observed a pregnancy after any of my sterilizing operations, I should have been much surprised if the tumor had proved to be a tubal pregnancy. But as her symptoms certainly pointed toward this condition and as her pain was not relieved by conservative treatment, I advised operation and carried it out, Nov. 25, 1918.

The technic of the sterilization had been perfect. The tumor belonged to the right ovary. Both ovaries were perfectly free from adhesions, the right one being almost the size of a fist, the left one the size of a hen's egg. The right tumor contained chocolate-colored fluid. The right ovary was removed entirely. The left ovary had healthy tissue at the base, and the tumor was excised and the ovary reconstructed by suture. The cyst of this side also contained chocolate-colored fluid. The patient made a good recovery.

Feb. 20, 1919, the patient returned. She had had her menstruation every twenty-three days since the operation, the last time February 11, lasting six days, copiously, with clots and pain in the left hypogastrium for two weeks. Examination detected now a cyst the size of a fist on the left side. The patient was advised to use hot baths. March 3, the swelling was the size of a hen's egg. As I could be positive that it was not a case of extra-uterine pregnancy, since I had observed the complete separation of the uterine cavity from the tubes and had recently seen that there was no infected tube, I simply burst the sac by sudden bimanual pressure. The maneuver produced no pain. I observed the patient for an hour, and in the absence of all untoward symptoms, I allowed her to go home. Sixteen days afterward she was still free from pain and had not menstruated. The left appendages were of normal size.

COMMENT

This was the first case in which I have deliberately broken such an ovarian swelling, a form of conservative treatment which I had contemplated for the relief of patients in whom operation was not desirable. As I had removed the right ovary from this patient; as she was less than 35 years old, and as I could feel certain of the nature of the cyst, this manipulation could be risked without undue hazard. If a patient who has been observed a sufficient period of time to establish the diagnosis on a sound basis, suffers from these alternating swellings and has considerable disturbance in consequence thereof but for some reason should not be operated on, this intentional rupturing of these cysts presents a simple method of relief, if only temporary. Otherwise, if the swellings continue to return, and especially, if ultimately the ovary does

not go down to normal size between the swellings, but remains large and produces pressure symptoms, then operation is indicated, in order to give permanent relief.

PATHOLOGY

While the question of treatment is comparatively easy to settle, a more difficult and interesting problem is presented by the pathology of the condition. Why do these ovaries swell? From the macroscopic and microscopic examination of these ovaries it is evident that the swelling has its seat in the corpus luteum and represents a cystic enlargement of this structure with contents of serum or blood. In the first two cases in which I operated, the ovaries were embedded in adhesions, and this suggested that the presence of the adhesions prevented the follicle from rupturing freely. But aside from the fact that everyday observation fails to show cyst formation in every case of adherent ovaries, the findings in the third case, reported here, prove conversely the possibility of cyst formation without any adhesions. However, of the cases that did not come to operation, of which a number have been observed for years presenting alternating swellings, a large majority presented adhesions.

The age at which the swellings occur was as low as 25 and (as in Case 1) as high as 48.

The relation of the swellings to the monthly periods is commonly so that the swelling is first noticed from eight to fourteen days before the menstruation and has more or less disappeared within three or four days after the menstruation. This periodicity caused the addition of the term "periodic" to the nomenclature of the clinical entity.

Many authors have reported periodic increase in the size of ovaries which were the seat of what they called chronic oophoritis; but I have not been able to find any description of a series of alternating cases anywhere in the literature. The microscopic findings in the organs removed in my operations resemble the descriptions of chronic oophoritis contained in the literature, but I fail absolutely to see any signs of inflammatory changes in the ovaries themselves, while the adhesions found on the outside of these ovaries can readily be explained independently of the ovarian condition (for instance, in Case 1 by the presence of an old appendical peritonitis).

The changes going on in these ovaries are dependent on the corpus luteum. Their effect may be simply due to the size of the cyst producing pressure symptoms, or, what is equally important, the effect is that of faulty corpus luteum function.

CHANGED CONCEPTION OF THE VALUE OF THE CORPUS LUTEUM

We have changed our conception of the value of the corpus luteum very much. Years ago the ovary was considered useful mostly for the production of ova. The corpus luteum was not understood. It was permissible then to consider it merely as a temporary false scaffolding which would keep the ovary from collapsing after the rupture of the follicle, if I may express it so crudely. Now we know that the ovary and the corpus luteum have special functions. We might compare the female sexual tract with a clock. The ovaries are the weights which make the whole machine go. The uterus might be compared to the hands and the corpus luteum to the regulating mechanism—say, the pendulum. The periodic function of the corpus luteum, same as the periodic swinging of the pendulum, keeps the appa-

ratus in rhythmic action indicated by the rhythmic menstruation. As soon as the pendulum gets out of order, the rhythm becomes disturbed; as soon as the corpus luteum becomes pathologic, we have irregularity of menstruation in one or the other direction. The function of the corpus luteum under pathologic conditions is a chapter which must be added to the old pathology.

CONCLUSION

It may be clear now why I have enumerated several types of puzzling clinical observations. It is evident that if we have such a patient with alternating periodic ovarian swellings and see her for the first time and break her cyst under our fingers, we cannot tell what we have broken. But when we are better acquainted with the abnormal periodicity of her ovaries, we can even go so far as to rupture her cyst intentionally and with beneficial results.

It may also become clear that Drs. A, B and C were all correct in their various diagnoses of right tumor, left tumor and no tumor, and that it might be wise to remember this clinical picture before upsetting the patient's confidence or injuring the standing or wounding the feeling of our brethren.

It may also be clear now how an irregularity of the corpus luteum may affect the menstrual function so that on the first examination a diagnosis of extra-uterine pregnancy may seem warranted, whereas a further acquaintance with the patient may (as for instance in Case 3) show the symptoms to be those of alternating periodic ovarian swelling.

ABSTRACT OF DISCUSSION

DR. EMIL NIAWK, Baltimore: The cases such as Dr. Ries reports are grouped under three special types, all attributed to some abnormality of corpus luteum structure. I think he is right in attributing this important rôle to the corpus luteum. That, of course, is the thing that undergoes cyclic change every month. The first case which he reported I think was simply a case of ruptured corpus luteum cyst. The second group of cases of which he spoke were those in which he found unruptured corpus luteum cysts. Such cases have been reported quite frequently in the literature, chiefly because they give rise to a picture simulating that of extra-uterine pregnancy. There are the symptoms of delayed menstruation, irregular or continuous bleeding and the presence of a mass. The most interesting group is the third, those cases in which was found the cystic condition regarded as due to the presence of corpus luteum cysts either with or without epithelial lining. I think it is open to question whether these were due to corpus luteum cysts or whether they were simple lutein cysts which are not genuine corpus luteum cysts. Such cases are best illustrated by the striking group of cases in which there are lutein cysts similar to those found in hydatid mole or chorionepithelioma. These cysts are not genuine corpus luteum cysts, and when we remove the hydatid cyst the tendency is for these ovarian cysts to vanish. Gravidum-um cells are not found in the genuine corpus luteum cysts.

DR. ALFRED BAKER SPALDING, San Francisco: The author spoke of these tumors appearing on one side and then on the other, accompanied by pain. I wondered whether in going back over the cases he did not find that patients had the large ovary without pain. That has been my experience. I have seen women with ovaries such as Dr. Ries described and have unfortunately operated on some of them, removing the ovaries. I have studied them in the laboratory and invariably found not only the corpus luteum cyst but that the ovary resembled an angioma. At operation I have seen the large veins running from these ovaries to form a varicocele. I have wondered whether many of the symptoms complained of might not be due to the varicocele that occurs

in the broad ligament rather than to the cyst. These patients have been very difficult to handle in the matter of giving relief. I have frequently treated them for a number of years with hydrotherapy, and I have sometimes referred them to colleagues who were using high frequency or electrical treatment, and they have been relieved. Only surgery will give such patients real relief—suspending the ovary in a hammock by bringing enough peritoneal fold over the uterine ligament to give that ovary a bed. This gives relief for a time. I have reoperated on a patient who had a recurrence of a retroversion because of an improperly done operation to hold the fundus forward, and I found that those folds had become strings, like those Kelly described in his old operation of ventral fixation. With a good fixation forward, the support of the ovary will relieve the patient of the symptoms and let the corpus luteum go on through its function as it pleases. So long as the patient is not in pain she does not care. Without a good support of the fundus forward I do not believe any support of the ovary will relieve a congestion which causes the varicocele which is the condition causing the pain.

DR. PETER B. SALATICH, New Orleans: I have been making a study of this subject for several years. A patient will often complain during menstruation of more pain on one side than on the other. Examination of these patients a few days before menstruation will show the ovary to be larger at that time than a week or two after menstruation. In all cases in which I have removed both ovaries I plant a piece of ovary between the fat and the fascia and in many of these patients two or three days or a week before menstruation the ovary enlarges to two or three times the size of the piece planted. Sometimes just before menstruation the ovary will stretch and be as large as a lemon and in a week or two afterward the swelling will disappear and there will be no more pain or swelling. I had one patient who refused operation. She would have considerable pain, at times with temperature elevation. Then, in two or three days there would be a discharge of pus from the vagina when the pain and swelling would disappear. This has occurred about half a dozen times, and finally the condition cured itself without an operation. You will find that the pain on the right side will come on every two or three months and that the menstruation will be more profuse and attended with greater pain than that of the previous month or two. Operation will probably show both ovaries to be cystic. The important point is that on the right side where the pain is greatest you will find that the ovary is probably worse than on the side where there is no pain. But if you are going to save the ovary on the side of which the patient complains, no relief is obtained; the pain will continue just as before. Therefore, I always make it a rule to study the patients carefully and remove the ovary on the side on which they do not complain of pain.

DR. EMIL RIES, Chicago: I wish to correct a misunderstanding. The swellings which I have described are not the swellings of an ordinary ovary, but often tumors the size of a fist or larger. There is not always pain; there may be just a little feeling of fullness. Sometimes I discover that the patient knows nothing about the presence of a tumor. The most important thing is that these tumors recur—not that there is a tumor. I am not talking of ordinary corpus luteum cysts—I am talking about returning tumors. The nature of the cysts was established by microscopic examination, of course. It is not necessary to go into the pathology of corpus luteum cysts. The important point is the return of the tumor. I am not speaking of the cyclic swelling of the ovaries mentioned in every good textbook. This is something new, not previously described anywhere.

Health Board Celebrates Centenary.—On March 18, the births and deaths department of the New Orleans Board of Health completed 100 years of service. In March, 1819, sixteen years after the Louisiana Purchase, the first death "That of a free man of color," was reported by the Board of Health of New Orleans. The first birth was reported March 25, 1919. The present recorder, P. Henry Latour, has held the position for forty-four years.

Clinical Notes, Suggestions, and New Instruments

TREATMENT OF SEASICKNESS

A. E. LEMON, M.D., SAULT STE. MARIE, MICH.

Major, M. C., U. S. Army; Surgeon, One Hundred and Twenty-Fifth Infantry

It has long been believed that seasickness is the result of the motion of the ship affecting the semicircular canals, the organ of equilibrium in the internal ear.

I was aboard the U. S. S. *Great Northern*, en route from Brest, France, to New York, May 2 to 9, 1919. This ship was carrying troops, and was making a record for the round trip to Europe. With her high speed and light forward ballast, although she pitched or rolled very little, she had a very pronounced plunging motion, with the rising and falling motion predominating. As a result of this accentuated rise and fall, about 90 per cent. of the troops, and a considerable number of the crew, were more or less seasick; and at least 700 were in very great distress.

I had put in three years in Newfoundland; had not been seasick for years, and was not sick at all on the trip to Europe, in February, 1918, when the sea was less smooth than on this trip. But as soon as we cleared from the harbor at Brest, I became, unexpectedly, very seasick. I had been careful to see to it that diet indiscretions, alcohol and lack of elimination were eliminated as a possible cause of seasickness in my case. And yet, at 4 p. m., May 4, I was more sea-

and was again relieved by repacking the ears. The treatment was so immediately and positively effective in the cases on this ship that the only possible cause of failure on other ships would seem to be the unlikely but possible existence of more than one variety of seasickness.

AN IMPROVEMENT OF THE AEROPLANE SPLINT

FRANK W. ROMAINE, M.D. (WASHINGTON, D. C.)

Captain, M. C., U. S. Army
CAMP UPTON, YAPHANK, N. Y.

During the European war, many varieties of splints came into vogue. Some of them were resurrected from the discard, while others combined old ideas with new positions and arrangements. Among the various mechanical supports is the "aeroplane" splint used for fractures of the surgical and anatomic necks of the humerus, gunshot wounds of the shoulder involving the joint, and wounds of the outer end of the clavicle and spine of the scapula. This splint has been used to great advantage and with much comfort to the patient, both before and after operative procedure. But as devised it does not meet all the requirements of the long convalescence of these types of cases. A later style is open to practically the same objections, as it does not permit of the lowering of the arm with support in the axilla, the point at which support is most needed.

Figure 1 (the original splint) shows the rigid support, desired in the first weeks of convalescence, to maintain the arm and forearm at right angles to the body.

Fig. 1.—Original type of aeroplane splint; rigid.

Fig. 2.—Second type of splint permitting lowering of arm by loosening thumb screw A; lowering occurs in the same plane as in rigid or first position.

Fig. 3.—Improved splint permitting horizontal arm; to be moved at any angle by loosening thumb screw E and sliding sleeve D up or down upright bar F. This is accomplished by hinges at points A and C.

sick than during the first twenty-four hours, with no indication of improvement. I felt a fine, indefinite sense of change of pressure on the ear drums, which, I may say, however, was not shown by a barometer in my room.

I reached for some sterile gauze, and, with the aid of a match, packed both external ear canals, packing against the eardrums. It took only a few minutes to find out that relief was immediate as soon as I had packed the gauze tightly enough so as to cause a decided sense of pressure in the ear canal.

I immediately began relieving others, being, officially, surgeon of troops aboard the ship, which gave me the right to treat every one I found sick. Although we were forty-eight hours out, I still found about 200 persons quite sick.

Further observation on the relation of the outer ear canal to seasickness shows that soldiers who were exposed to shell fire in Europe were almost without exception much more afflicted with seasickness coming back from Europe than they were going over. Surgeons on board ships carrying troops have told me that this observation is borne out in their experience. In my own case, I had both ear drums injured by shells exploding in two cases within 7 yards by measurement, and with only open space between me and the shell. I cannot otherwise account for the violent case of seasickness I suffered on leaving Brest, and which led, or rather forced me, to look for a new method of relief.

In collecting more information from those whom I was able to relieve on the trip across, I found several cases in which, after being relieved for several hours, the packing was removed from the ears, when the seasickness at once returned,

Figure 2 shows the splint devised to permit the lowering of the arm and forearm. In this type the arm and forearm are lowered en masse by loosening the thumb screw (Fig. 2 A) and allowing the upright rod to slide down the desired distance, whereupon the screw is tightened. This permits of a relaxation at a point where support is most desired, and of a general sagging of the arm, causing a greater strain where support is needed most. This splint has been found to be undesirable, uncomfortable and painful to the patient.

In the improved splint (Fig. 3) as devised during the war and used on war wounds of the shoulder involving the head of the humerus, the clavicle and the scapula, a happier result is obtained. A greater degree of comfort is afforded the patient, a rest is established for the arm and forearm, and support is maintained in the axilla. The lowering and raising of the arm and forearm are executed without disturbing the dressings or requiring the removal of the splint.

At the angle formed by the horizontal and perpendicular rods (Fig. 3) a hinge is made (A). A band of steel (B) three-quarters inch wide and 2¼ inches long is riveted to the horizontal rod 1¼ inches from A. At point C is hinged a band similar to the first band, 2¼ inches long, connected at an angle of 45 degrees with a sliding double sleeve (D), which is fitted with a thumb screw (E) permitting the lowering and raising of the sleeve and the consequent movement of the horizontal arm support. The upright (F) between the points A and G is roughened, permitting the thumb screw (E) to bite and hold firmly.

A TRIAL FRAME FOR EYE MALINGERING

FRANK ALLPORT, M.D., and JAMES R. SMITH, M.D., CHICAGO

In the detection of eye malingering we have adopted the old and simple method of inserting in the trial frame a strong convex lens on one side with a plano lens on the other, without the patient's knowledge of the relation of the lenses, and with rarely a suspicion that he is being subjected to a test for malingering. The strong convex lens, which excludes vision at a distance of 20 feet, is placed over the patient's good eye, with a plano lens over his supposedly injured or amblyopic eye. Then, with both eyes open, the patient is asked to read the letters on the test chart. Any resulting vision is very evidently the vision which the patient obtains with the supposedly defective eye. This is a very simple test, and demonstrates to what extent the patient sees with the eye in question.

There are numerous devices for the detection of malingering, many of which are complicated and confusing in their application. We have devised a convenient reversible spectacle frame, with a plus 6 sphere on one side and a plano

Trial frame for eye malingering.

lens on the other, which constitutes, to all intents, a pair of spectacles. There is a cross or X bridge which allows the glasses to be easily reversed and adds very much to the ease with which the test can be made. It is also more or less deceptive to the patient, even though he mistrusts that he is being made the subject of a malingering test. If one suspects that a person is malingering, one may simply place the trial frame on the face, with the convex lens over the good eye and the plano lens over the supposedly injured eye. One should observe the patient very closely to see that he does not close either eye, but that the test is made with both eyes wide open. As before stated, any resulting vision will represent the vision of the defective eye. An advantage of this trial frame is the ease with which it can be manipulated; that is, it can be removed and reversed, adding confusion to the patient.

Malingering is often difficult to detect, especially if a patient has been instructed to be suspicious of ocular examinations. 7 West Madison Street.

AN ANOMALOUS ABDOMEN

THOMAS B. NOBLE, M.D., and SCOTT R. EDWARDS, B.S., M.D.
INDIANAPOLIS

Intra-abdominal anomalies are relatively rare. This conclusion is warranted, at least, by the literature. The fact that they are diagnosed, except in exceptional instances, only at operation or necropsy, limits our knowledge concerning their frequency of occurrence. Anomalies are encountered most often in the genito-urinary apparatus of the female. The case here reported is that of a woman having two distinct anomalies of the genito-urinary system, and one of the alimentary system.

REPORT OF CASE

History.—Mrs. J., a married white woman, aged 37, had had chronic constipation and long continued epigastric pain, accompanied by sterility. The present illness began two days before her admission to the hospital, with vomiting and epigastric pain. On admission the patient presented symptoms of acute intestinal obstruction. She was almost in collapse. Her appearance was cachectic, and a distinct tumor was palpable, which was taken to be the head of the colon.

Operation and Result.—A tentative diagnosis of cancer of the cecum with obstruction was made and she was operated

on immediately under ether anesthesia. A wide exposure, made by a midline incision, revealed, to our surprise, these conditions: There was an absolute failure of rotation of the colon. The right kidney lay in the right iliac fossa with the renal pelvis lateral; the vessels came off just above the bifurcation and passed over the ventral surface to dip down into the kidney, and the ureter passed beneath the lower pole of the kidney. The uterus was approximately 1.5 cm. in width and 3 cm. in length; the remnant of the genital cord passed down as a fibrous cord to an infantile vagina. This rudimentary uterus was suspended by a very lax ligamentary support, and lay in the sac of a left inguinal hernia.

The acute symptoms were due to the character of the anomaly of the large bowel. The stomach and the first 5.5 centimeters of the duodenum were intensely injected and distended with gas. The condition terminated at a point of kinking in the duodenum at the beginning of a duodenal mesentery. The duodenum was freely movable on this mesentery and was not covered by peritoneum, but continued in a curve to the left into the jejunum uncovered by the transverse colon.

The weight of the small bowel dragging down on the duodenum was responsible for the kink. The entire length of the small bowel was approximately 3.5 meters. The entire course of the colon was to the left of the midline, the cecum lying in the left iliac fossa.

An anastomosis was made between the jejunum and the stomach around this duodenal kink, and the abdomen was closed. Vomiting persisted, notwithstanding every effort to control it. The patient died on the third day following the operation.

SIR WILLIAM OSLER AT SEVENTY— A RETROSPECT

No physician occupies a higher place in the esteem and affection of the English-speaking medical profession than Sir William Osler. For many years his name and his words, written or spoken, have carried an appeal to the mind and heart of physicians as no one else's, and they do so still today. To explain fully this matchless power, this intellectual and moral force, is a far greater task than we would pretend to attempt at this time; but in the interest especially of the rising generations of physicians, the present occasion seems a suitable one on which to point out some of the chief landmarks along the road traveled by the beloved and honored septuagenarian on the way to his high place.

The friends of student days in Toronto and at McGill University in Montreal have recorded that he followed no traditional course, but worked much in the hospital and especially the postmortem room, and that unlike most of his fellow students he troubled himself apparently but little about examinations and mere book knowledge. His graduation thesis on topics in pathologic anatomy was awarded a special prize "because it was greatly distinguished for originality and research." After two years of study abroad, he began to teach pathology in Montreal. He was then 25 years old. Before long he was teaching medicine in the wards also, and he seems quickly to have given himself so completely over to teaching, anatomic and clinical observations, and literary and medical society work as to leave little time for private practice and the cultivation of opportunities to earn money, caring apparently but little about the morrow. Many papers were published these years: those on prodromal rashes in smallpox, on blood platelets, and on infectious endocarditis may be mentioned as examples of the more important. From the first he made a hit as a successful teacher who aroused enthusiasm and stimulated independent work. One more significant fact in regard to the Montreal phase of Osler's career should not be overlooked, namely, the deep and actively helpful interest in the student himself which

has characterized his relations to students and young physicians throughout the succeeding years.

It is remarkable how early he attained certain fixed and dominant characteristics that have contributed alike to his usefulness and distinction. Any adequate account of just how various early influences worked together to give such a distinctive and definite bent to Osler's career from its very inception has not been made. It will be an interesting story. Palmer Howard and James Bovell, Canadian physicians of rare quality, are said to have influenced his medical work and outlook more than others. In 1884, Osler went to Philadelphia as professor of clinical medicine in the University of Pennsylvania Department of Medicine. His new colleagues were not a little astonished at first because he steadily turned aside all temptations to private practice in the usual sense but remained strictly teacher and consultant, thus securing the desired leisure for study in hospital, laboratory and library. His demonstrations in the pathologic society drew to him the younger men of the profession especially, an example of sharing the stores of observation all too little followed by leading teachers of clinical medicine and surgery, with an occasional exception like Fenger in Chicago. Many notable articles were published, and while in Philadelphia another side of Osler not yet referred to revealed itself fully, namely, his keen interest in medical history and biography and his gift for letters. In "Who's Who," bibliography is given as his sole recreation.

From this period dates the beginning of a series of addresses and essays of high literary merit: now rich with results of diligent search in medical scriptures, always hopeful and cheery, inspired by lofty ideals and an instinctive spirit of kindliness, they belong, many of them, more to the permanent "literature of power" than to the short-lived "literature of knowledge," and every physician should have them in his library. He has stimulated greatly the interest in our own medical history, and we owe to Osler vivid sketches of the lives and work of early leaders of the profession in this country—Nathan Smith, Bartlett, Jackson, Bigelow, Alonzo Clark, Gerhard and others—with whom it was his ambition to be ranked. "The chief desire of my life has been to become a clinician of the same stamp with these great men, whose names we all revere and who did so much good work for clinical medicine."

As no one before him in this country, Osler illustrated that years of hospital work and observation give better equipment for teaching clinical medicine than practice as ordinarily pursued; hence, when the Johns Hopkins Hospital was opened in 1889, he was the first choice for the head of the department of medicine. And now began the most productive and fruitful period in his professional life. His cherished ambition to build up a great clinic in this coun-

JOUR. A.M.A., JULY 12, 1919

Wm Osler

try was to be fulfilled. Under the liberal and enlightened policies of the new institution in Baltimore, he rapidly organized a model medical clinic, one of the best, and the first and long the only one of its kind in this country. Here medical students were taken into the wards as units in the working force of the hospital; young physicians were trained through graduated services for higher careers in clinical medicine, and knowledge advanced by systematic study and investigation. Beloved by colleagues, assistants, students, he inspired them, as a colleague has said, with extraordinary stimulus to high endeavors. The result was a great contribution, sorely needed at the time, to medical education and to clinical medicine, which makes one of the brightest pages in our annals.

The work done by Osler and his associates during this period is now woven into the fabric of modern American medicine. It was a wonderfully productive period. His influence as writer and speaker expanded; he preached a vigorous gospel of sanitation, particularly with reference to typhoid fever; he promoted the work of medical societies and libraries, and entered deeply into the life and interests of the profession generally. "With the general practitioner throughout the country my relations have been of a peculiarly intimate character," and few if any have enjoyed in such remarkable degree the warm personal friendship and admiration of physicians everywhere. He was the high priest of lofty ideals, harmony and friendly cooperation. Always the close, kind friend of his students and assistants, many a fumbling beginner has been gladdened unexpectedly by his generous encouragement.

In 1905, Osler accepted the Regius professorship of medicine in Oxford University. While we have not been able to follow his many activities so closely as when he was here, we have had continuous evidence that his work has gone on with undiminished vigor, and that his relations to the profession at large and his interest in its welfare have undergone no other change than in the place of immediate manifestation. Neither wealth nor fame has turned him away from the calm course he laid out for himself while still a very young man. His recent utterances, in a chapter on the treatment of disease, on the exploitation through impudent advertising of pseudoscientific preparations of questionable value by powerful manufacturing pharmacists have the familiar Oslerian ring and hit the bull's eye in the center. In place of a more or less noticeable tendency to therapeutic vagaries he would place "a stern, iconoclastic spirit which leads, not to nihilism,

but to an active skepticism born of a knowledge that recognizes its limitations and knows full well that only in this attitude of mind can true progress be made."

And now we must take leave again of our friend and teacher. The American Medical Association sends him its heartiest congratulations on his seventieth birthday, and warm assurances of gratitude and affection. And to our young men, coming on the scene, we would recommend careful heed of these words from Osler's response at the farewell dinner tendered him at New York, May 2, 1904:

I have had three personal ideals: One to do the day's work well and not to bother about tomorrow. You may say that is not a satisfactory ideal. It is; and there is not one which the student can carry with him into practice with greater effect. To it more than anything else, I owe whatever success I have had—to this power of settling down to the day's work and trying to do it well to the best of my ability, and letting the future take care of itself.

The second ideal has been to act the Golden Rule, as far as in me lay, toward my professional brethren and toward the patients committed to my care.

And the third has been to cultivate such a measure of equanimity as would enable me to bear success with humility, the affection of my friends without pride, and to be ready when the day of sorrow and grief came to meet it with the courage befitting a man.

MY BIRTHDAY GREETINGS TO COLLEAGUES
AND OLD STUDENTS OF MCGILL, PENNSYLVANIA,
JOHNS HOPKINS AND TO MY MANY
FRIENDS IN THE UNITED STATES AND CANADA.

WM. OSLER.

THE PHYSIOLOGIC COST OF CHEWING

The act of mastication has lately attained new prominence in human physiologic routine from two different circumstances: first, the vigorous advocacy of thorough mastication as the basis to hygienic well-being. It is largely owing to the propagandist energies of the late Mr. Horace Fletcher that the doctrine of deliberate mastication has been widely preached; and "fletcherism" has gained many adherents among that omnipresent group which is searching for the secret of a better existence through improved health. One of the claims made in favor of thorough mastication as advocated by Fletcher is that the extreme comminution of the food and the more effective insalivation promote the digestion and utilization of the nutrients. Despite the plausibility of this argument there is an abundance of experimental evidence to show that the nutrients in the common food products are absorbed in large measure even under ordinary habits of eating. It is exceptional to find less than 90 per cent. of the digestible nutrients utilized; and for the familiar fats and carbohydrates the records approach almost perfection. The residual fecal masses are normally devoid of more than small quantities of digestible nutrients. That which constitutes the output by the bowel comprises indigestible residues, refuse matter from alimentary secretions, and bacterial residues. These are not unutilized nutrients.

Furthermore, comparative investigations of the actual utilization of the nutrients by persons who on one occasion "bolted" and on another occasion "fletcherized" the same diets have given no experimental justification for the assumption of improved absorption as the effect of the more thorough mastication. Obviously it is a physiologic desideratum to comminute moderately at least some of the meats and carbohydrate foods that enter into the customary human dietary. In certain diseased conditions, comminution of the food is an indispensable requisite. However, so far as the fad-dist features and the extreme claims of unique benefits are concerned, we cannot forego quoting the remark of an extremist in the other direction. "Fletcherism," he writes, "is permissible in those easy-going lackadaisical individuals whose tastes are gently epicurean and who possess the desires of a Lucullus minus the means. Let those benighted harmless souls chew and champ to their heart's content, for they, poor beings, need some fad, and this one can harm no one unless it be themselves. But to busy men who are shouldering the cares of government, commerce and science, and whose strenuous impetuosity moves them to act quickly, whose every act is intense and every movement a flash—to such individuals, fletcherism is a thorn in the flesh."¹

In the second place mastication has become conspicuous in this country through the widespread use of chewing gum. Some time ago a distinguished chemist² remarked in a public address that if the Rockefeller Institute is spending to good advantage about half a million dollars per annum for medical research, the chewing gum bill of the United States would easily support half a dozen Rockefeller Institutes. Coaxed by the insidious suggestions of advertisements and encouraged by the public example of bankers and ministers, physicians and judges, men and women from all classes have joined the ranks of the mastication army. The lasting odor of mint has begun to compete with that of onions and garlic in certain groups of our population. We shall not venture to discuss the alleged virtues of chewing gum. The reports of its help in allaying thirst for the boys in the trenches can scarcely be used in support of the use of chewing gum in the ordinary walks of life. Nor can the alleged presence of pepsin in certain brands be emphasized as a universal panacea. Amid all the uncertainty as to the physiologic effects of chewing gum one fact has been clearly demonstrated. Benedict and Carpenter³ of the Nutrition Laboratory of the Carnegie Institution of Washington in Boston have found that as a result of chewing gum the basal metabolism may be increased more than 17 per cent.

This has a further bearing on the doctrine of "fletcherizing." If prolonged mastication can necessitate an excess heat production equivalent to nearly one fifth of the basal metabolism, it is easily seen, to quote the Boston physiologists, that any advantage gained from a possible increase in the digestibility of the food is more than compensated by the increase in heat production. The conception, they add, of an increase in the digestibility and in the utilization of the energy of foodstuffs as a result of prolonged mastication thus finds no support in fact.

NICOTIN IN CIGAR SMOKE

Nicotin, which exhibits a toxicity of high degree, is volatile. Why the tobacco which contains it does not cause greater evidences of pronounced poisoning than are observed in the ordinary smoker has been a mystery. The traditional explanation has been that nicotin is destroyed in the process of smoking, and that the combustion products, real or conjectured, are far less toxic in their character than is the tobacco alkaloid itself. There can no longer be any doubt, however, that the nicotin is by no means completely burned up in smoking, for there is valid evidence that more than one third of the volatile poison can be recovered in the smoke.⁴

Various schemes have been employed or recommended to eliminate the nicotin menace of tobacco without making it necessary to give up its use. Among these are the production of so-called nicotin-free cigars. They have never attained any recognition in this country, although serious attempts have been made to introduce them in some of the European countries. One product has represented the result of extracting the tobacco to remove the alkaloid. As other valued aromatic properties of the plant are thereby likewise removed, such detoxicated tobacco has never attained popularity. Another method has consisted in "fixing" the alkaloid by a treatment which forms the insoluble nicotin tannate. Tobacco treated in this way may, on ordinary chemical analysis, show a low content of nicotin; but this does not prove that the nicotin may not be liberated into the vapors in some degree when the tobacco is smoked. Experiment shows, in fact, that it actually is. Another procedure has been to introduce iron chlorid near the butt end of the cigar with the object of making it retain some or all of the volatile nicotin that passes through this portion as the smoke proceeds into the mouth of the smoker. Here, too, critical investigation has revealed the failure to prevent the exit of nicotin, at least in such cigars of this type as have been offered for sale to date.

Storm van Leuven² of Utrecht has prepared another surprise for the unsuspecting smoker. He has made an investigation of the actual nicotin content of cigar smoke collected under conditions comparable to those that prevail in the actual performance of smoking, in which some of the products of combustion are dissipated into the air without absorption and only a part is collected in the mouth. According to the observations made by the Dutch pharmacologist, not only were some of the current "harmless" sophisticated cigars obtainable in Holland quite as rich as were ordinary cigars in their yield of nicotin, but it was also brought out that no correlation between the supposed "strength" of cigars and the toxicity of their vapors could be established. The common distinction between mild and strong cigars was found to be no index of the content of nicotin that passes into the smoke; nor could the color or even the nicotin content of the leaf be depended on to foretell the outcome of the actual smoke test.

If this be correct, it follows that the current designation of tobacco as mild or otherwise probably depends in large measure on factors of flavor or aroma as well as on assumed physiologic effects that it may bring about. What constituents are responsible has not been determined. The feature for emphasis here is the seemingly well substantiated assertion that cigars are not always what they seem—so far as nicotin is concerned.

COMMERCIAL THERAPEUTICS

A report of the Council on Pharmacy and Chemistry that appears elsewhere³ in this issue deals with another attempt to foist on our profession a series of essentially secret preparations whose therapeutic value has not been scientifically demonstrated. Grotesquely extravagant claims are advanced as to the therapeutic potency and range of action of substances of whose nature and effects we have no trustworthy information. Physicians are advised to use—and many undoubtedly are using—these alleged remedies in the treatment of diseases in which delay in the proper kind of treatment may be of the greatest danger to the patient. As stated, there is available no reliable information regarding the effects of these substances when they are introduced in the human body. They may have no effect whatever, or they may produce more or less direct injury; in either case there is the chance that damage, even irreparable to the patient, may result because rational treatment is withheld.

If we accept the statement that the preparations are largely vegetable proteins, it is a fair inference that, under certain conditions, they may

cause a febrile reaction of the same general nature as that caused by other foreign proteins when injected into the body. We know that such reactions are not without danger and that the treatment of certain infections by induced reactions to foreign proteins is strictly an experimental procedure to be undertaken only under very special conditions. There is, therefore, no known valid reason why a physician should assume the responsibility for using these alleged remedies in the treatment of his patients; there is a very obvious reason why he should not—the therapeutic instructions of "the House of Merrell, always interested in the progress of plant therapy" to the contrary notwithstanding. It is the old story of exploiting physicians through commercial pseudoscience; of trading on the credulity of the profession to the detriment of the public. As Osler⁴ recently protested so vigorously:

Some time ago a pamphlet came from X and Company, characterized by brazen therapeutic impudence, and indicating a supreme indifference to anything that could be called intelligence on the part of the recipients. That these firms [manufacturing pharmacists] have the audacity to issue such trash indicates the state of thralldom in which they regard us. And I would protest against the usurpation on the part of these men of our function as teachers. Why, for example, should Y and Company write as if they were directors of large genito-urinary clinics instead of manufacturing pharmacists? It is none of their business what is the best treatment for gonorrhoea—by what possibility could they ever know it, and why should their literature pretend to the combined wisdom of Neisser and Guyon? What right have Z and Company to send on a card directions for the treatment of anemia and dyspepsia, about which subjects they know as much as an unborn babe, and, if they stick to their legitimate business, about the same opportunity of getting information? For years the profession has been exploited in this way, until the evil has become unbearable, and we need as active a crusade against the pseudoscience in the profession as has been waged of late against the use of quack medicines by the public. We have been altogether too submissive, and have gradually allowed those who should be our willing helpers to dictate terms and to play the rôle of masters. FAR TOO LARGE A SECTION OF THE TREATMENT OF DISEASE IS TODAY CONTROLLED BY THE BIG MANUFACTURING PHARMACISTS, WHO HAVE ENSLAVED US IN A PLAUSIBLE PSEUDOSCIENCE.

What shall the profession do to protect itself against this humiliation—to throw off the credulity that extols pseudoscience and makes commercialized empiricism financially profitable? Osler says the remedy is obvious: "Give our students a first-hand acquaintance with disease, and give them a thorough practical knowledge of the great drugs, and we will send out independent, clear-headed, cautious practitioners who will do their own thinking and be no longer at the mercy of the meretricious literature, which has sapped our independence." Excellent! But must humanity wait a generation? Why not stop this evil at once? The American Medical Association has provided the means whereby this can be done, if physicians will only make use of it—the Council on Pharmacy and Chemistry.

THE MEASURE OF METABOLISM

Owing to the efforts of a number of American investigators, many facts regarding metabolism in man have been convincingly demonstrated. The rôle of muscular activity in creating an extra demand for energy as derived from food fuel has long been recognized. Even some of the minor activities in which muscles are engaged transform energy in amounts that are readily measurable by the newer methods. The energy expended by an infant in crying, the work done in rising from the reclining posture, the muscular work involved in chewing gum—these and similar activities can be measured and their cost to the body expressed in terms of converted calories. Less well known is the stimulatory effect of recently ingested food on the metabolism. As Benedict¹ and his collaborators have lately reminded us, in reviewing the present state of knowledge in this field, heat production is greatly increased after eating, and the amount of increase is closely dependent on the nature of the food consumed. For example, the metabolism of a subject may be increased by 25 per cent. after a meal consisting chiefly of carbohydrates, but by as much as 45 per cent. after a heavy protein meal. Furthermore, size, age and sex also play a part in determining the chemical exchanges in the body.

Lately it has become quite customary to place emphasis on bodily dimensions, measured by the extent of body surface, in evaluating the degree of metabolic changes. Harris and Benedict² have insisted that the correlations between body weight and metabolism and between body surface and metabolism are of approximately the same magnitude. Body weight and body surface have, therefore, the same value in indicating the basal metabolism of the subject. Realizing that weight, stature and age all have independent significance for predicting the metabolism of a person, Harris and Benedict have succeeded in devising mathematical formulas based on numerous actual observations in calorimetry, whereby the basal metabolism of a person can be estimated with a fair degree of accuracy. Such methods, even though they involve a fund of technical biometric information such as the average physician cannot be assumed to possess, promise to furnish useful criteria for determining the existence of disturbances of metabolism in certain diseases. They thus amplify the admirable contributions to clinical calorimetry that have emanated in recent years from the Russell Sage Institute of Pathology in New York City.

The Carnegie Institution contributions seem to establish clearly that there is a difference in the basal

metabolism of men and women. Quoting the results ascertained, they show that the average daily basal heat production of the 136 men investigated is 1,632 calories, whereas that of the 103 women studied is 1,349 calories. Thus the daily heat production of women is about 300 calories less than that of men. But women are smaller than men. If correction for body size is made by expressing heat production in calories per kilogram of body weight, it is 25.7 calories in the men as compared with 24.5 calories, or 1.2 calories per kilogram less, in the women. The men show an average daily heat production per square meter of body surface of 925 calories as compared with 850 calories, or 75 calories less, in the women. This difference is well marked through the period of adult life. The measure of metabolism is the fundamental requisite in establishing the "standards" of food requirement in human nutrition.

Current Comment

A NEW MEMORIAL TO PASTEUR

Soon after the conclusion of the armistice, a new and apparently very successful dramatic experiment was attempted in Paris. A dramatist well known heretofore as a specialist in "amorous psychology," M. Sacha Guitry, has had presented a play without a female character, a single-minded portrayal of a hero of humanity, Louis Pasteur³; in the opinion of critics, at least, it is an entire success. Pasteur is shown in a sort of aureole of hero worship as patriot, as scientist, and as passionate well wisher of mankind in general and in particular. He brooks no opposition to what he knows to be right, he fights bitterly against the conservatism which would nullify his progress, and when successively he receives all the honors which France and other countries can bestow, he is grateful and modest. The third act offers the exciting occasion of the first antirabic inoculation of the little boy, Joseph Meister, and the event is utilized with considerable effect to emphasize the sympathetic warmth of Pasteur's nature as the fitting complement of scientific ability. Pasteur's speech is full of the expression of his ideals, taken in part from actual public addresses. "Do not search for those who will give you advice; look rather for those who will set you an example." "Labor and persevere"—it is the keynote of his life, of a life in which the only element of importance is his work, which, however, is always actuated by the high purpose of improving the lot of man. The final words of the play, written in the year 1918, are the words of Pasteur himself: "And I believe absolutely that knowledge and peace will triumph over ignorance and war, and that men will work together, not to destroy, but to build." The piece is interesting, not only as an effort to present a great man of science to popular applause, but also

because it has apparently met the approval of critics and theater goers. The dramatic aspects of Pasteur's life are of necessity pushed to the fore, but it does not seem that his character is distorted.

VITAMINS AND TRENCH FOOT

Vitamins are being referred to frequently at present in the discussion of some obscure diseases which puzzle the clinician. French observers¹ correctly point out that among the symptoms attributable to a deficiency of certain vitamins in the diet are those of scurvy and neuritis. They assert that, especially in the earlier period of the war, soldiers deprived of fresh foods rich in vitamins not infrequently exhibited symptoms that might be designated as "prescorbutic," as well as neuritic manifestations approximating some of the features of clinical beriberi. When, owing to prolonged dietary deficiencies, a latent sort of scorbutic or neuritic tendency developed, the conditions were offered for superimposing added factors which manifested themselves in such peripheral difficulties as trench foot. In other words, the primary defect was a polyneuritic and cutaneous disturbance consequent on improper nutrition. The more specific features and local injuries then developed because they found in the ill nourished tissues a suitable location. Bruntz and Spillmann attribute the decrease in trench foot and related maladies in the succeeding seasons to improved rationing as the fundamental prophylactic factor. It is an interesting speculation to place nutrition in the forefront of the causes bringing about the improved condition of the soldiers as the war progressed. However, no one can overlook the improvements in other aspects of military hygiene which also contributed to making trench life less unendurable and damaging as the lessons of experience were gradually brought to bear on the situation.

WILLIAM OSLER'S BIRTHDAY

By happy coincidence, the date of issue of this number of THE JOURNAL is the day on which the medical professions of Great Britain and the United States combine to honor Sir William Osler on his seventieth birthday. The occasion is fraught with good omens, for no other physician has done more to bring peace and concord among his fellows "where'er his stages may have been," and no living man has done more to unify the medical professions of the United States and the mother country. An impressive record of his achievement is afforded in the nineteen contributions which make up the July number of the *Bulletin* of the Johns Hopkins Hospital, each of them written by a colleague or pupil whose knowledge of Osler is intimate enough to be authoritative. Not least of these is the exhaustive and accurate bibliography of Osler's 730 contributions to the literature of medicine (1870-1919) by the librarian of the Johns Hopkins Hospital. It is significant that the two

papers so far published in 1919 are both of them contributions to clinical medicine. Through his own contributions and his personal influence, Osler has given a greater stimulation to the study and investigation of medical history in this country than any other living man. Those who have seen his unrivaled collection of original texts and documents relating to epoch-making discoveries and advances in medicine predict that its catalogue, informed as it will be with Osler's big humanism, will take its place as one of the great monuments of medical bibliography. The story of Osler's life is a simple record: Canadian born (1849), the son of an Ontario clergyman, and M.D. of McGill University (1872), a graduate student in London clinics and German laboratories (1872-1874), lecturer and professor of the Institutes of Medicine at Montreal (1874-1884), and successively professor of medicine at the University of Pennsylvania (1884-1889) and the Johns Hopkins University (1889-1894), Regius Professor of Medicine at Oxford since 1904. The highest honors in the Anglo-Saxon profession have been his.

SPORTING POSTMORTEM

Thus, Jess Willard via "patent medicine" advertisements in 1916:

"I have often taken Nuxated Iron and I have particularly advocated the free use of iron by all those who wish to obtain great physical and mental power. Without it I am sure that I should never have been able to whip Jack Johnson so completely and easily as I did, and while training for my fight with Frank Moran, I regularly took Nuxated Iron, and I am certain that it was a most important factor in my winning the fight so easily."

Has Nuxated Iron lost its strength, or did Jess lose interest in that product as soon as his testimonial became ancient history? The exploiters of the nostrum have asserted that it makes "Iron Men"; but then, recent events have shown that three rounds with a towel-waving finale is also a great "iron men" producer. 'Tis an ill wind that blows no one good. The Toledo episode has deprived the gentlemen who sell Nuxated Iron of the pulling power of one of their testimonials, but they still have others. For instance, the Hon. William E. Mason, congressman at large from Illinois, has extolled the nostrum for overcoming that "horrible tired feeling one cannot describe." There must be a lot of fight fans who need something in that line.

State Tuberculosis Work.—In Idaho a bill providing for two district sanatoriums, the only bed provision for tuberculosis in the state, has been enacted into law. In South Dakota provision has been made for county nursing and county hospital care for the tuberculosis patient. Oklahoma has enacted a law providing for two sanatoriums for white patients and one for negroes and a bureau of tuberculosis in the state department of health together with adequate provision for the care of these patients in counties. Every one of these laws is the result of organization, in New Mexico by the New Mexico Public Health Association, in Idaho by the Idaho Association for the Study and Prevention of Tuberculosis, in South Dakota by the Red Cross Seal Commission of South Dakota, in Oklahoma by the Oklahoma Tuberculosis Association.—*Journal of Outdoor Life*.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending July 3, there were 12,731 officers in the Medical Corps, a decrease of 413 from the previous week. The Medical Reserve Corps contained 2,808 officers. The total number of physicians discharged since the beginning of the war is 20,192.

Army Medical Department Appropriations

The Army Appropriation Bill as finally passed by Congress carries an appropriation of \$4,500,000 for the purchase of general supplies of the Medical Department of the Army. Other items carried are: for hospital care, Canal Zone Garrisons, \$500,000; for the Surgeon-General's Library, \$20,000; for the preservation of specimens for the Army Medical School, Washington, \$10,000. An appropriation of \$350,000 for the purchase of twenty-six acres of land adjoining Walter Reed Hospital, Washington, for the final location of the Army Medical School, Surgeon-General's Library and the Army Museum, and for the improvements now on the land to be purchased, was also finally adopted. This appropriation was very greatly desired by the authorities of the Medical Department.

Award of Croix de Guerre

HERRERT D. PORTERFIELD, Major, M. C., U. S. Army, Red Oak, Iowa, assistant to the chief surgeon of the Third Army Corps, has been awarded the croix de guerre.

"A medical officer who displayed remarkable devotion to duty since the F Division joined the front. Participated in battles of Cantigny, Soissons, St. Mihiel, Argonne, Sedan. Volunteered in May 26, 1919, to be attached to a front line first aid station and showed conspicuous gallantry in rendering first aid under heavy shell fire. For the operations July 18 to 22, he distinguished himself in crossing many areas swept by violent machine gun and shell fire, in order to supply the first aid stations of the front line. During the operations, October-November, 1918, he volunteered and frequently visited the front line first aid station and inspired the medical personnel by his coolness and utter disregard for danger."

Awards of Croix de Guerre, with Palm

The following is a list of officers who, while in the military or naval service of the United States, have been awarded the French croix de guerre, with palm:

MARVIN CAPPEL, Captain, Medical Corps, Ninth Infantry, Second Division, Alexandria, La.
FREDERICK W. BLACK, Major, Medical Corps, Twentieth Infantry, First Division, Paris-Strasbourg, Pa.
WILLIAM EARLE BOYCE, Captain, Medical Corps, Medical Detachment, Thirtieth Infantry, Third Division, Flat Woods, Tenn.
ERVIN T. DRAKE, First Lieutenant, Section 145, United States Army Ambulance Service, Franklin, N. H.
MARCEL E. DUCASSE, First Lieutenant, Section 546, United States Army Ambulance Service.
SAMUEL C. GURNEY, Lieutenant-Colonel, Medical Corps, Third Division, Detroit, Mich.
CHARLES W. CONFORT, Major, M. C., U. S. Army, New Haven, Conn., sergeant of the One Hundred and Second Infantry, for being continually present on the front line, administering first aid to the wounded under violent artillery and machine gun fire.
JAMES C. ELLIS, Captain, Ambulance Company No. 37, 3d Division.
WILLIAM J. LOSH, First Lieutenant, Section No. 553, United States Army Ambulance Service.
WILLIAM YORKE STEVENSON, First Lieutenant, Section No. 625, United States Army Ambulance Service.

Awards of French Croix de Guerre, with Bronze Star

The following is a list of persons, who, while in the military or naval service of the United States, have been awarded the French croix de guerre, with bronze star, and are authorized to wear on their Army uniforms, according to Army regulations, that decoration or a ribbon indicative thereof:

CHARLES J. COLE, Jr., Captain, Medical Corps, Field Hospital No. 25.
PHILIP CONLON, 1st Lieut., Medical Corps, 3d Battalion, 9th Inf., 1st Division.
DEIDLEY T. DAWSON, Captain, Medical Corps, 146th Inf., 3rd Division.
CLARENCE C. DEL MARVELLE, 1st Lieut., Medical Corps, 1st Field Hospital, 1st Division.
FRED B. LAANS, Captain, Medical Corps, 1st Field Hospital, 2d Division.

HARLOW G. FARMER, Major, Medical Corps, Field Hospital No. 15, 2d Division.

ELLIOTT LEE, 1st Lieut., Section 632 United States Army Ambulance Service.

WILLIAM F. McFEE, 1st Lieut., Medical Corps, 9th Inf., 2d Division.

WILLIAM C. MEACHAM, Captain, Medical Corps, Ambulance Company No. 1, 2d Division.

EDWARD MOORE, 1st Lieut., Section 512, United States Army Ambulance Service.

HENRY M. MOORE, Captain, Medical Corps, Field Hospital No. 23, 15, 2d Division.

LUKE B. PECK, Major, Medical Corps, 7th Inf., 3d Division.

ARTHUR H. RUGGLES, Major, Medical Corps, Field Hospital No. 1, 2d Division.

Awards of Croix de Guerre, with Gilt Star

The following is a list of officers who, while in the military or naval service of the United States, have been awarded the French croix de guerre, with gilt star.

RICHARD DERBY, Lieutenant Colonel, Medical Corps, Second Division, New York.

JAMES H. ERLENBACH, Captain, Medical Department, One Hundred and Third Infantry, Twenty-Sixth Division, Boston.

OLIVER R. AUSTIN, Major, Medical Department, Twelfth Field Artillery, Second Division, Aberdeen, Wash.

STANLEY F. BERRY, Major, Three Hundred and Sixteenth Sanitary Train, Ninety-First Division, Oakland, Calif.

LOUIS H. COCKERHAM, First Lieutenant, Ambulance Company No. 15, Medical Corps, Second Division, Palestine, Texas.

LEO J. CRUM, First Lieutenant, Sanitary Detachment, One Hundred and Twenty-Sixth Infantry, Thirty-Second Division, Kalamazoo, Mich.

DWIGHT DICKINSON, Jr., Assistant Surgeon, Fifth Regiment, United States Marine Corps, Second Division, Washington, D. C.

CHARLES MAXWELL, M. C., Major, Medical Corps, Twelfth Field Artillery, Second Division.

TRAVIS S. MORING, Assistant Surgeon, Sixth Machine Gun Battalion, Second Division, M. C., U. S. N.

REUEL A. PIERCE, First Lieutenant, Medical Detachment, One Hundred and Third Infantry, Twenty-Sixth Division, Taunton, Mass.

CARROLL P. PRICE, First Lieutenant, Medical Department, Seventeenth Field Artillery, Second Division, Harrodsburg, Ky.

ABRAHAM J. F. THOMAS, First Lieutenant, Medical Corps, Ambulance Company No. 1, Newburgport, Mass.

OLIVER E. VAN ALVEA, First Lieutenant, Medical Corps, Ambulance Company 16, Chicago.

HENRY P. GLENDENNING, Second Lieutenant, Medical Corps, Company F, 5th Regiment, United States Marine Corps, 2d Division.

DAVE W. MACCLAIN (deceased), Second Lieutenant, Medical Service, 5th Regiment, United States Marine Corps.

JOHN D. SOUTHWORTH, First Lieutenant, Medical Corps, Ambulance Company No. 15.

Awards of Croix de Guerre, with Silver Star

The following is a list of officers who, while in the military or naval service of the United States, have been awarded the French croix de guerre, with silver star, and who, under the provisions of the act of Congress approved July 9, 1918 (Bulletin No. 43, W. D., 1918), are authorized to wear on their Army uniform, according to uniform regulations, that decoration or a ribbon indicative thereof:

CHARLES ST. JOHN BUTLER, First Lieutenant, Section 638, United States Army Ambulance Service, M. C., U. S. Navy.

JOHN E. KUYKENDALL (deceased), Captain, Three Hundred and Sixteenth Train, Ninety-First Division, Eugene, Ore.

FLOYD D. LEWIS, Captain, Three Hundred and Sixteenth Sanitary Train, Ninety-First Division, Silvertown, Ore.

CARL W. SHAFFER, Captain, Medical Corps, Fifteenth Field Artillery, Second Division, Woodstock, Va.

JOHN G. STROHM, Major, Division Surgeon, Ninety-First Division, Portland, Ore.

THOMAS JOHNSON SUMMEY, First Lieutenant, Medical Corps, Ambulance Company 23, Second Division, Bedford, N. C.

Award, Posthumous, of Distinguished Service Cross

By direction of the President, the distinguished service cross was awarded posthumously by the commanding general, American Expeditionary Forces, for extraordinary heroism in action in Europe, to the following named officers of the American Expeditionary Forces:

HERBERT D. RYMAN, Captain, Medical Corps, 107th Field Artillery. For extraordinary heroism in action near St. Gilles, France, August 17, 1918. While administering first aid to a wounded soldier he was himself mortally wounded. Refusing aid, he assisted in rendering first aid and directing the treatment of three other soldiers. Though weakened by loss of blood, he showed utter disregard for his personal danger, refusing to accept treatment until the other wound-1

had been cared for. Next of kin, Mrs. Cora Belle Ryman, wife, Mount Pleasant, Ill.

HARRISON B. WEBSTER, Major, Medical Corps, 47th Infantry. For extraordinary heroism in action near Bois de Brieuilles, France, September 26 to October 12, 1918. After seeing that his personnel was functioning properly, he went fearlessly to positions in the front lines. When stretcher bearers were unable to handle the large number of casualties, he personally took a light German wagon to the front lines and gathered the wounded. His personal bravery was an inspiration to his men throughout his service. He was killed by shell fire on Oct. 12, 1918. Home address, Mrs. Harrison B. Webster (wife), 145 South Street, Northampton, Mass.

Awards of Distinguished Service Medal

By direction of the President, the distinguished service medal has been awarded by the commanding general, American Expeditionary Forces, to the following-named officers of the United States Army for exceptionally meritorious and distinguished services, as set forth after their names:

Col. DEANE C. HOWARD, United States Army. For exceptionally meritorious and conspicuous service. In organizing and administering the Division of Sanitation and the Sanitary Inspection Service of the Office of the Surgeon-General of the Army he contributed greatly to the efficiency of the military service.

Col. CARL R. DARNALL, United States Army. For exceptionally meritorious and conspicuous service. He has rendered especially meritorious and distinguished service in organizing and developing and administering the Supply Division of the Medical Department, and it is due to his foresight and ability that new sources of medical supplies were developed in this country so that adequate quantities of material were always available for use with the sick and wounded of the Army.

Col. FREDERICK F. RUSSELL, United States Army. For exceptionally meritorious and conspicuous service. He organized and directed the Division of Laboratories and Infectious Diseases of the Surgeon-General's Office during the present war and thereby contributed in great measure to the efficiency of the military forces.

Col. EDWIN P. WOLFE, United States Army. For exceptionally meritorious and conspicuous service. He systematized and controlled the distribution of medical supplies with so much foresight and good judgment that his service was able to meet promptly all the emergencies in the United States as they occurred.

Col. REUBEN B. MILLER, United States Army. For exceptionally meritorious and conspicuous service in the reorganization and administration of the personnel branch of the Office of the Surgeon-General of the Army during the present war. He thereby contributed greatly to the proper care of the sick and wounded and thus increased the efficiency of the Army.

Col. VICTOR C. VAUGHAN, United States Army. For exceptionally meritorious and conspicuous service. During his service in the office of the Surgeon-General his contributions of advice and information have been of great value to the Army in connection with the control of communicable diseases. During the recent epidemic of influenza, in particular, his work was of extreme value.

Col. WILLIAM H. WELCH, United States Army. For exceptionally meritorious and conspicuous service. From his rich experience in scientific medicine, sanitation, public health and medical education he helped materially in guiding the medical profession both in and out of the Army safely through many difficulties of war.

Lieut. Col. GLEN I. JONES, Medical Corps, United States Army. For exceptionally meritorious and conspicuous service. While surgeon of the 10th Division during the epidemic of Spanish influenza he not only command his far-sightedness in providing hospital facilities and his energetic and exceptionally efficient action in directing the care of patients resulted in a large reduction of mortality. His services show a rare devotion to duty in that though himself a sufferer from the disease, his efforts were unabated.

Col. JAY W. GRISSINGER, Medical Corps, United States Army. For exceptionally meritorious and distinguished services. As division surgeon of the 42d Division, and later as chief surgeon of the 1st Army Corps during its operations on the Marne and in the St. Mihiel and Meuse-Argonne offensives, he displayed qualities of leadership, high professional attainments, and rare judgment in energetically directing the work of the sanitary units under his control in providing front line hospitalization and evacuation facilities for our sick and wounded in the field.

Lieut. Col. RICHARD P. STRONG, Medical Corps, United States Army. For exceptionally meritorious and distinguished services. Possessed of the highest professional qualifications and actuated by zealous devotion to duty, he has rendered services of inestimable value to the American Expeditionary Forces, notably as president of a board appointed to investigate the cause of trench fever, a disease which has caused serious losses to the effectiveness of the allied armies. The scientific research of this board under his skilful direction led to the discovery of the means by which trench fever is transmitted and in the establishment of effective measures for its prevention.

Major-Gen. ROBERT E. NOBLE, Medical Corps. For exceptionally meritorious and conspicuous services. He had immediate charge of the Personnel Division of the Surgeon-General's Office and solved the problem of getting medical officers into the Army during an increase from 1,500 at the beginning of the war to 30,000. He also had charge of the Hospital Division of the Surgeon-General's Office, handling both of these large responsibilities with conspicuous success.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

NOTE.—In the following list, L. signifies Lieutenant; C., captain; M., major; L. C., lieutenant-colonel; Col., colonel, and B. G., brigadier-general.

Asst. Asst. Surg. W. F. REASNER, relieved at Leavenworth, Kan., proceed to Portsmouth, Va., for duty.

Asst. Asst. Surg. WILLIAM H. WALSH, proceed to Markleton, Pa., to inspect the Markleton Sanatorium, to determine its desirability for the treatment of tuberculosis.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ILLINOIS

Society Visits General Hospital.—The visit of the Aux Plaines Branch of the Chicago Medical Society to U. S. General Hospital No. 28, Fort Sheridan, June 25, was participated in by more than 500. The party was welcomed by William N. Bispham, Col., M. C., U. S. Army, commander of the hospital, a surgical clinic was held in Ward 52, and then the party was conducted through the entire hospital, including the educational department.

Violators of Medical Practice Act Fined.—E. H. Madison of 3333 Calumet Avenue, Chicago, practicing medicine as a "magnetic healer," and Mrs. Anna Marlick of East St. Louis, practicing as midwife, were arrested by the Illinois Department of Registration and Education for violating the Medical Practice Act, and were each fined \$50 and costs. Mrs. Anna Comfort of East St. Louis was also arrested for violating the Medical Practice Act and was fined \$100 and costs.

Personal.—Dr. Florence R. Kremer has resigned as assistant physician at the Kenilworth Sanatorium, to accept an appointment with Chesapeake and Ohio Hospital, Clifton Forge, Va.—Dr. Mark Greer, Vandalia, has been awarded the Military Cross by the British government for bravery in dressing wounded men under shell fire in France, in September, 1918.—Dr. Emmett A. Garrett, Peoria, has been discharged as lieutenant-colonel, M. C., U. S. Army, after nearly a year of service abroad, and has returned home.—Dr. Henry B. Brown, Lincoln, has been appointed local surgeon of the Chicago and Alton Railroad, succeeding Dr. Frank M. Ewing, deceased.

Chicago

Dope Pedler Arrested.—Ann Scott Rusling was arrested, June 30, by Dr. William H. Sage and his agents, charged with the illegal sale of narcotic drugs, which she is said to have secured by obtaining blank prescription forms and forging the names of Chicago physicians to them.

Dispensary Clinics.—Organized and financed by the National Catholic War Council, clinics have been opened at Mercy Hospital, and at the Hospital of St. Mary of Nazareth, and a third clinic will be opened at St. Joseph's Hospital, about August 1. A social service department is operated in connection with each clinic. The clinic is open from 9 a. m. to 4 p. m., and eleven specialties are covered. The Mercy Hospital clinic is housed in the rooms of the late Dr. John B. Murphy. In the Hospital of St. Mary of Nazareth, rooms have been reconstructed for this purpose, and in St. Joseph's Hospital ten rooms in the new wing of the building have been set apart for the use of the clinic. The staff of the hospital in each case is the staff of the clinic.

Personal.—Dr. Evans A. Graham has been appointed professor of surgery in Washington University, St. Louis, succeeding Dr. Fred T. Murphy, resigned. Dr. Graham will be head of the department of surgery and will have charge of the surgical service in Barnes Hospital and Children's Hospital, St. Louis.—Dr. Earl V. Hill of the sanitary bureau of the department of health has been appointed acting chief sanitary inspector, succeeding Mr. Charles B. Ball, who has been given seven months' leave of absence that he may serve in the housing commission of the Y. M. C. A., in France.—Dr. Norval H. Pierce has been elected president of the American Laryngological Society.—Major Charles H. Parkes has just reached New York from overseas, after two years' service in the Medical Reserve Corps.—Dr. William G. Lee has returned from abroad and resumed his practice.

INDIANA

Personal.—Major Paul F. Martin, Indianapolis, accepted an offer of the commissioner to Europe of the American Red Cross to become consulting surgeon to Red Cross hospitals in Russia.

Sanatorium for Four Counties.—County officials of Ia Grange, Noble, Steuben and De Kalb held a meeting at

Rome City, June 23, looking toward the establishment of a district tuberculosis sanatorium.

Death of Mrs. Bulson.—Mrs. Eva Maude Bulson, wife of Dr. Albert E. Bulson, Fort Wayne, a woman of rare intellectual attainments, who had been ill for more than three years with heart disease, died at her home, June 27.

Veneral Disease Clinics.—Surg. William F. King, U. S. P. H. S., who is in charge of the venereal disease clinic at Indianapolis, has appealed to the city board of health and city council to appropriate \$7,500 that the clinic may be kept in full operation.—Howard County council, June 24, made a special appropriation of \$1,500 for the establishment of a clinic for venereal diseases.

Fresh Air School.—The report of the Theodore Potter Fresh Air School, conducted on the Technical High School grounds, Indianapolis, was made public recently by Mary A. Meyer, executive secretary of the Marion County Tuberculosis Association. The records made for the school year of 1918-1919, in the advancement of the health of the children, were considered wonderful by the officials of the tuberculosis association. The records were somewhat lower, however, than in previous years, because of the influenza epidemic and because for a part of the year the schools were closed while soldiers occupied the buildings. Fifty-four pupils were enrolled in the outdoor school during the year. Several made remarkable gains in weight and practically all made some gain. The highest gain made by a single child was 30½ pounds.

Eight-Hour Day for Doctors.—The Vanderburg County Medical Association, Evansville, has voted to go on an eight-hour day basis, as nearly as possible, and to increase the fees about 50 per cent. A committee has been appointed to work out a scale of prices.—Lafayette and West Lafayette physicians have adopted a new schedule of fees, which is a decided advance over charges that have prevailed there for the last few years. Office calls which have been \$1 are \$2 under the new schedule. House calls which are now \$2 have been raised to \$3, and calls between 7 p. m. and 7 a. m. are raised to \$4. Telephone consultation and advice calls for a fee of \$1. Calls outside of the city are to be charged for at the rate of \$1 a mile for the first ten miles and 50 cents for each additional mile, plus \$3. Consultation will cost \$15 in Lafayette and West Lafayette. Outside of these cities the charge will be \$15 plus the same mileage as in the case of calls.

MARYLAND

Infantile Paralysis Appears.—Two cases of infantile paralysis and one death from the malady were reported to the health department during the past week. The death occurred in a local hospital. Officials of the health department said that there was no indication of a return of infantile paralysis this summer, although there may be some sporadic cases and an occasional fatality. The city's general death rate was higher last week than it has been for some time, 206 persons having died from all causes, compared with 203 for the corresponding period of 1918. For a month or two the weekly record of deaths has been under 200. Births for the week totaled 220.

Personal.—Drs. Hugh Hampton Young and William S. Thayer, Baltimore, are to go abroad. Dr. Young to go over with the British and French army authorities problems met with during the war as director of urology for the A. E. F. and Dr. Thayer to do some work for the National Research Council. Both expect to be away for about two months. Dr. Young, in addition to his work with the French and British authorities, will attend an international health conference to be held in Brussels the latter part of this month. During his absence, Drs. John T. Geraghty and William A. Frontz will conduct his department at the Brady Institute.—Col. Henry Page, a regular army medical officer, whose home is in Princess Anne, Md., has succeeded Lieut.-Col. Harry S. Purnell as commandant at the U. S. Army General Hospital No. 2, Fort McHenry, the appointment taking effect July 4.

Health Department Warns of Eyestrain.—The health department has issued an appeal for the cooperation on the part of parents in correcting this summer physical defects among 8,000 schoolchildren, that these schoolchildren may do more effective work when they return to their books in the autumn. These defects are serious enough to need medical attention and advice for their correction. For the most part, it is said, the children are suffering from eyestrain,

making it impossible for them to see the blackboards in the schoolrooms. Fully 400 are back in their grades because of this defect. Others have had teeth, adenoids and diseased tonsils. The officials in charge of this work are most anxious through the cooperation of the parents and the children to have these deviations from the normal corrected as far as possible during the vacation period, and to accomplish this purpose the school nurses will continue their work throughout the summer. The children deserve from their parents and from the community proper opportunity to be relieved of the handicaps. To this end, each of these children has been given a card indicating the defect or defects needing correction and advising the parents to secure medical attention. It is entirely in the hands of the parents to make their own choice of the private physicians or the dispensaries. The health department school nurses will arrange for the children's visits to a medical consultation on the request of the parents.

MASSACHUSETTS

Therapist Found Guilty.—Ernest Carreiro, a "therapist" of Boston, charged in three counts with practicing medicine without being registered, and in three others with holding himself out to be a practitioner without being registered, is said to have been found guilty and fined \$100 in each of the six counts. He appealed and was held in bonds of \$1,500 for the superior court.

Hospital Notes.—June 25, the base hospital at Camp Devens was virtually closed. Since the institution was opened in September, 1917, more than 40,000 patients have been admitted to this institution. One of the buildings of the hospital group is to be maintained as a cantonment hospital for the time being.—The Boston Floating Hospital has opened its twenty-fifth season. Dr. Hyman Greene, Boston, will be the resident physician, and Miss Sarah A. Eagan will continue as superintendent of nurses.—An addition is immediately to be built to the Worcester City Hospital at a cost of \$70,000.

Personal.—Dr. Howard A. Streeter, Pittsfield, state health officer for the Berkshire district, was appointed, June 1, 1919, chief of the subdivision of venereal disease, state department of health.—Dr. George H. Bigelow, Frammingham, has returned home from service in the Medical Corps overseas, and has been appointed temporary epidemiologist in the state health department, succeeding Dr. Bernard W. Carey, Winthrop, who has been made head of the division of communicable disease.—Dr. John S. Hitchcock, Northampton, has resigned as director of the division of communicable disease in the state department of health.—Dr. Emily C. MacLeod, Boston, has been selected as a member of a unit of women physicians to assist in the relief of Serbia.

MISSOURI

Unlicensed Practitioner Prosecuted.—Proceedings have been brought against Louis Tien-nti, Kansas City, charged with practicing medicine without a license.

Occupational Therapists Incorporated.—The Missouri Association of Occupational Therapy, recently organized in St. Louis, has been incorporated to teach occupational therapy as an aid in the reconstruction of disabled soldiers and persons injured in industrial establishments. Dr. G. Canby Robinson, St. Louis, is president of the organization.

Medical Veterans Form Association.—The Medical Veterans of the World War living in southwestern Missouri held a meeting for organization at Springfield, June 4, and elected the following temporary officers: president, Dr. William A. Delzell, and secretary, Dr. Horace A. Lowe, both of Springfield. Invitations have been sent to all physicians in the southwestern part of the state who served in the Army, Navy or Public Health Service to attend the next meeting to be held in Springfield, July 9.

Personal.—Dr. Fred T. Murphy, St. Louis, professor of surgery in Washington University since 1911, commander of Base Hospital Unit No. 21, and later on duty with the American Red Cross in France, was tendered a dinner by the faculty of the medical school of Washington University on his retirement from the faculty. — Dr. William M. Gardner, Chillicothe, has been elected president of the local board of health.—Dr. Samuel W. Chandler, Cassville, has been elected president of the Southwestern Missouri Medical Society.—Dr. John W. Good, Fordland, was operated on at the Springfield Hospital, June 14.—Dr. William B. Sisson, Kahoka, has gone to Siberia where he will be engaged in work for the American Red Cross.

NEW JERSEY

Hospital Staff Organized.—The hospital staff of the Salem County Memorial Hospital, at its meeting for organization, elected Dr. Clifford M. Sherron, Salem, president, and Dr. William H. James, Pennsville, secretary.

War Surgeons Organize.—A New Jersey society of Medical Veterans of the World War was organized at Spring Lake, June 27. Dr. Henry B. Costill, Trenton, medical aid to the governor in selective service work, was chosen president; Dr. W. Blair Stewart, Atlantic City, secretary and treasurer; and Drs. John C. McCoy, Paterson; Alexander Marcy, Jr., Riverton, and Britton D. Evans, Morris Plains, vice presidents. There are 2,028 physicians eligible for membership out of 3,100 in the state, as follows: 814 from the Army, 28 from the Navy and 1,164 from selective service boards.

NEW MEXICO

Personal.—Mrs. Nina Otero-Warren, Santa Fe, has been appointed chairman of the New Mexico State Board of Health, succeeding Holm O. Bursum, resigned.—Dr. Oliver T. Hyde, Albuquerque, has been appointed a member of the board in place of Dr. John F. Pearce.

Medical Examiners Organize.—At the annual meeting of the state board of medical examiners, held in Santa Fe, Dr. James A. Massie, Santa Fe, was elected president; Dr. Creighton H. Ferguson, Tucumcari, vice president, and Dr. Robert E. McBride, Roswell, secretary-treasurer.

NEW YORK

Personal.—Dr. G. Herbert Carter, Huntington, has been elected president; Dr. Irving F. Barnes, Oyster Bay, vice president, and Dr. James H. Shawe, Huntington, secretary-treasurer of the North Shore Medical Association.—Dr. William A. Bing, Canandaigua, has been appointed superintendent of the Ontario County Tuberculosis Sanatorium, Oakmont, succeeding Dr. Stoughton R. Wheeler, Fast Bloomfield.

Alumni Election.—At the annual meeting of the Alumni Association of the Medical Department of the University of Buffalo, held in Buffalo, June 19 to 21, under the presidency of Dr. William F. Jacobs, '08, Buffalo, the following officers were elected: president, Dr. John A. Stapleton, '91, Rochester; secretary, Dr. Abraham H. Aaron, '12, Buffalo (re-elected); treasurer, Dr. Harry N. Feltes, '04, Buffalo, and trustee, Dr. William F. Jacobs, '08, Buffalo.

Health Conference.—The health conference held at Saratoga Springs, June 24 to 26, showed a registration of more than 1,000 health officers, physicians, nurses and public health workers besides many officials and staff members of the state health department and interested visitors. All phases of public health work were discussed by experts of international reputation. Much information was given regarding the work contemplated by the health department. A model health center occupied a suite of six rooms at the Grand Union Hotel. Here was conducted a public tuberculosis clinic, a clinic for the examination and treatment of persons afflicted with venereal disease, exhibits of child welfare work, a laboratory and a health officers' office. The healthmobile, an automobile built specially for the health department in carrying on public health education, was exhibited. This car is equipped with a stereopticon and moving picture machine run by power developed by the automobile and contains a number of exhibits showing the value of maintaining health and the prevention of infection. It is planned to send this automobile with a lecturer into sparsely settled communities.

Results of Health Survey.—The May issue of *Health News* is entitled the "Health Administration Number" and gives the results of the recently completed survey of health administration in the cities of New York state. This survey has served to call the attention of municipalities to the excellencies and deficiencies of their health departments. Certain defects were found to be nearly universal. "Among these were the inclusion under the health department of plumbing inspection, garbage collection, and similar activities, a vicious substitute, since a community was thereby led to believe it was spending a dollar per capita for health, whereas it might be spending but a fraction of that amount for proper health functions." The second defect was found in the lack of coordinated effort between public and private agencies, leading to a waste of public funds through failure to pursue a sound and sensible policy. Another defect and one that had a marked influence on the general efficiency of the health department, was the lack of adequate records and the failure

to make adequate use of them when they existed. It is pointed out that to secure appropriations the health department should be able to show its need, and the best way to do this is to show the amount, character, and desirability of its work.

New York City

Incorporate Rheims Hospital.—Supreme Court Justice Donnelly has approved the incorporation of the American Memorial Hospital which is to be erected at Rheims, France, under the auspices of the American Fund for French Wounded. Three hundred thousand dollars has already been raised toward the \$450,000 required for the first wing of the hospital.

Dr. Ward Liable for Fraud.—Dr. Francis R. Ward, director of the so-called "Electro-Medical Scientists," with offices in Brooklyn and New York, is said to have been held liable by Justice Marks, in the Sixth District Municipal Court, in an action for fraud and deceit brought by Julius B. Grond, a former patient. Judgment was awarded Mr. Grond for \$100 and costs.

Registration of Drug Addicts Goes into Effect.—Beginning July 7, every drug addict in this city must register with the state department of narcotic drug control at 128 Prince Street, and must obtain a dosage card before he can have any drug prescribed for him. This card bears the name, address and description of the addict, and the name of his or her occupation and employer. The addicts will be known by number. It is believed that this card system will make it impossible for the addict to obtain a prescription from one physician and to go to another physician and get another prescription. Physicians are obliged, when an incorrect dosage card is presented to them, to keep it, report the holder and return the card to the department office in this city. A new set of rules issued by the department of narcotic drug control sets forth in detail the system to be followed.

Personal.—Dr. William E. Studdiford has resigned the professorship of gynecology and obstetrics at the University and Bellevue Hospital Medical College in order to succeed Dr. Edwin Bradford Cragin, deceased, as head of the Sloane Hospital for Women.—Dr. Frederic C. Holden, Brooklyn, has been appointed professor of obstetrics and gynecology at the University and Bellevue Medical College and head of the gynecologic service at Bellevue Hospital to succeed Dr. Studdiford.—Dr. Walter T. Dannreuther has been appointed assistant professor of gynecology in the New York Post-Graduate Medical School and Hospital.—Dr. and Mrs. Howard Canning Taylor have sailed for Cuba.—Dr. Edward S. Godfrey, Jr., Albany, N. Y., epidemiologist to the division of communicable disease of the state department of health, has returned from France, where he has been connected with the American Red Cross in the capacity of chief of the health inspection service.—Dr. Angelo L. Soresi has returned to New York after four years' service in the Italian army.

NORTH DAKOTA

New Officers.—The twenty-third annual meeting of the North Dakota State Medical Association was held at Grand Forks, June 23 to 25, under the presidency of Dr. Edgar A. Pray, Valley City, and the following officers were elected: president, Dr. William P. Baldwin, Casselton; president-elect, Dr. Fred E. Ewing, Kenmare; vice presidents, Drs. Harley E. French, University, and Eric P. Quam, Bismarck; secretary, Dr. Hezekiah J. Rowe, Lisbon (re-elected); treasurer, Dr. William F. Sihler, Devils Lake; delegate to the American Medical Association, Dr. Edgar A. Pray, Valley City; alternate, Dr. Alexander J. McAnnell, Minot, and counselors, Drs. George F. Drew, Devils Lake; Lee B. Greene, Edgeley, and Ole A. Knutson, Buxton, for three years; Drs. Edward M. Ranson, Minot; Frederick L. Wicks, Valley City; LeRoy G. Smith, Medina, and Charles MacLachlan, New Rockford, for two years, and Paul H. Burton, Fargo, Francis R. Smyth, Bismarck, and John E. Countryman, Grafton, for one year. The society also recommended to the governor the following names for appointment to the state board of medical examiners: Drs. Gustavus J. McIntosh, Devils Lake; Victor J. LaRose, Bismarck, and Frank W. MacManus, Williston.

OHIO

District Supervisors Needed.—Eight physicians experienced in public health work are being sought by the state department of health to fill vacancies of district health supervisors at salaries of \$2,500 a year.

Public Health Stations Established.—The American Red Cross has established thirteen public health stations in Cincinnati under the supervision of the board of health at which

any person may consult a physician and have a thorough physical examination made without expense.

Personal.—Dr. John R. McDowell, Columbus, director of the division of tuberculosis of the state department of health, who has been on leave of absence for military service for two years, has returned to his work in the state health department.—Dr. Robert J. Jones, Greenfield, has been appointed division surgeon of the Baltimore and Ohio system.—Dr. William S. Baldwin, Lorain, who has been engaged in child welfare work for the American Red Cross in Jerusalem, reached New York on his return, July 2.—Dr. William H. White, Cleveland, lost his fight for reinstatement as chief medical examiner for the state industrial commission, when the supreme court reversed the decision of the Franklin County court, June 24.—Dr. Leroy B. Humphrey, Akron, has been appointed captain, M. C. Ohio, N. G., and assigned to the 14th Infantry.—J. C. Eberts, health officer of Chillicothe, has resigned.—Dr. Harry H. Myers, Shelby, has been appointed medical and welfare director of the plant of the Ohio Brass Company, Mansfield.

PENNSYLVANIA

Philadelphia

Money Raised for Italian Hospital.—Approximately \$80,000 was raised at the Forrest Theater, June 29, in a campaign for \$500,000 for the construction of a hospital and orphanage for Italians, in this city. The location of the hospital has not been decided.

Movies to Aid Tuberculosis Fight.—To bring forcibly before the people the menace of tuberculosis and to educate them in the best methods of combating the disease, the Philadelphia Tuberculosis Committee will stage a moving picture educational campaign during the summer.

Red Cross Supplies to Hospital.—More than 100 packing cases filled with bedding and surgical supplies left over at the end of the war, have been turned over to thirteen hospitals in this city and one in Chester, by the Southeastern Chapter of the American Red Cross. Hospitals receiving the supplies are: Lying-In Charity, Preston Retreat, Woman's Hospital, Woman's Homeopathic, Gynecean, Salvation Army, Philadelphia General, Jefferson, Chestnut Hill, Rush, St. Vincent, Jewish Maternity, City Maternity and Chester.

Health Department Training Camp.—Dr. Edward Martin, state health commissioner, has planned a state-wide organization of the 6,000 who are in the employ of the state health department and the first summer camp established by that department for intensive training was opened at Mount Alto, June 22. The first course terminated, July 2, and, July 6, a second group began its course of training. The plan of operation is to ask each of the 6,000 members of the health department in the state to secure ten additional volunteers from those who until recently were identified with welfare work during the war period. Each of these groups of ten will be instructed by a graduate of the course at Mount Alto.

WASHINGTON

Personal.—Dr. Harry Vanderbilt Wurdemann, Seattle, recently chief of the eye, ear, nose and throat section of the base hospital at Camp Lewis, Wash., has been commissioned major, M. R. C. U. S. Army.

Discourage Contract Service.—The Spokane County Medical Society, at its meeting, June 12, adopted an amendment to the rules providing for discontinuance of contract service excepting with interstate railway companies.

Graduate Medical Lectureship.—The University Extension Service of the University of Seattle announces the third annual graduate medical lectureship to be held in Seattle, July 14 and 18. Dr. Dean D. Lewis, Chicago, will give five lectures on surgery and Dr. Charles Lyman Greene, St. Paul, will give five lectures on medical diagnosis. Both of these lecturers have been on duty for a long time at important military posts. A series of clinics and laboratory demonstrations will be given during the same period. For this course there is a fee of \$10.

WISCONSIN

Personal.—Dr. Bruno L. Schuster, Albany, N. Y., has resigned as full-time health officer of Wausau.

New County Officers.—At the last meeting of the Manitowish County Medical Association, held in Manitowish, Dr. Jobo M. Kelley, Cato, was elected president, and Dr. Erwin C. C. Cary, Reedsville, secretary-treasurer.

CANADA

Dominion Physicians Meet.—The fiftieth annual meeting of the Canadian Medical Association took place in Quebec City, June 25 to 27. Dr. Jasper Halpenny, Winnipeg, delivered the address in surgery, and Dr. William S. Thayer, Baltimore, the address in medicine. Dr. Robert E. McKeelnie, Vancouver, was elected president, and the next annual meeting will take place in that city in 1920.

Licenses Revoked.—A number of Ontario physicians have been suspended by the Ontario Medical Council and their licenses to practice revoked from three months to a year for writing too many prescriptions under the Ontario Temperance Act. Several others have been summoned before the Ontario License Board and warned that their prescriptions will not be filled if they persist in abusing their privilege under the Act.

Personal.—Dr. Ezra H. Adams, Toronto, has been appointed medical health officer to the American Border District recently created by special act of the Ontario legislature.—Prof. T. Brailsford Robertson has resigned as head of the department of biochemistry of the University of Toronto. He is returning to the University of Sydney, Australia, his alma mater, where he succeeds his father-in-law as head of the department of physiology.—Major Hutton, R. A. M. C., will soon return to Canada and will accept the appointment of medical officer of health for Brantford.—Col. Francis A. C. Scrimger, V. C. Montreal, was recently given a case of cutlery by the governors of the Royal Victoria Hospital.

GENERAL

Personal.—Charles W. Richardson, Col. M. C. U. S. Army, gave a dinner at his suburban home near Washington, D. C., June 20, in honor of the British and French delegates to the American Medical Association.—Richard P. Strong, Col. M. C. U. S. Army, Cambridge, Mass., has been appointed acting director of the bureau of hygiene and public health of the League of Red Cross Societies.

Meeting of Examining and Licensing Boards.—At the twentieth annual meeting of the New England Federation of Examining and Licensing Boards, under the presidency of W. Scott Nay, Underhill, Vt., as the guests of the Rhode Island State Board of Health, in Providence, June 27, the advisability of annual registration of physicians was discussed at length, the consensus of opinion being in favor of the plan. Dr. R. Morton Smith, River Point, was elected president of the federation, and Samuel H. Colwell, Boston, secretary-treasurer.

Surgeons Elect Officers.—At the annual meeting of the American Surgical Association held at Atlantic City, N. J., June 16 to 18, under the presidency of Dr. Lewis S. Pilcher, Brooklyn, the following officers were elected: president, Dr. George E. Brewer, New York; vice presidents, Drs. John Fairbairn Binnie, Kansas City, Mo., and Alexis Carrel, New York; secretary, Dr. John H. Gibbon, Philadelphia; treasurer, Dr. Charles Howard Peck, New York; recorder, John H. Jopson, Philadelphia, and counselor, Dr. Lewis S. Pilcher, Brooklyn. St. Louis was selected as the next place of meeting.

Federation of Labor Supports Scientific Research.—At the recent meeting of the American Federation of Labor, the following resolution was adopted:

Resolved, By the American Federation of Labor in convention assembled that a broad program of scientific and technical research is of major importance to the national welfare and should be fostered in every way by the federal government, and that the activity of the government itself in such research should be adequately and generously supported in order that the work may be greatly intensified and extended; and the secretary of the federation is instructed to transmit copies of this resolution to the President of the United States, to the president pro tempore of the Senate, and to the speaker of the House of Representatives.

Medical Museum Association Meeting.—The twelfth annual meeting of the American and Canadian sections of the International Association of Medical Museums was held at Atlantic City, June 14, under the presidency of Prof. Oskar Klotz, Pittsburgh, and the following officers were elected: president, Prof. Oskar Klotz, Pittsburgh; vice presidents, Drs. William M. Late Copelin, Philadelphia; Harold E. Robertson, Minneapolis, and Howard I. Karns, Cleveland; secretary-treasurer, Dr. Maud E. S. Abbott, Montreal (re-elected), and assistant secretaries, Louis Gross and E. Shanley, Montreal. A report was presented on the standardization of the American made supply of square glass museum

jars, and symposiums on war museums and influenza and pneumonia followed.

Red Cross Items.—Lieuts. Jack Butterfield, Evanston, Ill., W. A. Fox, Buffalo, and Major E. A. Fish, Minneapolis, members of the Ambulance Section, American Red Cross, in France, have been decorated with the Croix de Guerre for bravery under fire.—Miss Alice Fitzgerald, formerly of New York and Boston, has been appointed chief nurse of the American Red Cross Forces overseas.—Shipment to Siberia of ambulance bodies, and surgical supplies valued at \$348,850 has been authorized by the Red Cross on recommendation of Major Kendall Emerson, Worcester, Mass., who reported that the commission in Siberia is in urgent need of gauze, nonabsorbent cotton, absorbent cotton and cellulose cotton.—Fifty carloads of surgical dressings have been sent from Red Cross headquarters in Paris to Roumania.

Air Service Officers Organize.—Medical officers of the Air Service, U. S. Army, held a meeting for organization in Atlantic City at the time of the session of the American Medical Association, and organized the Air Service Medical Association of the United States, electing the following officers: president, John O. McReynolds, Col., M. C., U. S. Army, Dallas, Texas; vice presidents, Theodore C. Lyster, Col., M. C., U. S. Army, Rockefeller Institute, New York; Eugene R. Lewis, Col., M. C., U. S. Army, Dubuque, Iowa; Isaac H. Jones, Col., M. C., U. S. Army, Philadelphia; William H. Wilmer, Col., M. C., U. S. Army, Washington, D. C., and Albert E. Truby, Col., M. C., U. S. Army, Washington, D. C.; secretary, John P. Gallagher, Major M. C., U. S. Army, Philadelphia; treasurer, Robert S. McCombs, Major, M. C., U. S. Army, Philadelphia, and historian, E. C. Schneider, Major, M. C., U. S. Army, Mineola, L. I., N. Y.

Bequests and Donations.—The following bequests and donations have recently been announced:

Medical Department of the University of Louisville, Ky., \$5,000, payable at the rate of \$500 annually, for the equipment of a research laboratory at the hospital, a donation by a member of the medical faculty.

Washington University School of Medicine, St. Louis, a grant of \$5,000 for investigation of hypertrichiasis, from an anonymous donor. The committee in charge of the grant consists of Dr. G. Canby Robinson, dean, Dr. Martin F. Engman of the department of dermatology, and Dr. Charles H. Danforth, of the department of anatomy.

Federation of Jewish Charities and Pennsylvania Hospital, Philadelphia, each \$1,000 by the will of Rose Strauss.

Bryn Mawr, Pa., Hospital, \$5,000 by the will of Mrs. Emma C. A. Simpson, Philadelphia.

Jewish Hospital, Philadelphia, an income of an estate of \$30,000 for the maintenance of three beds, by the will of Moses J. Blatz.

Ashington, Pa., Memorial Hospital more than \$7,000, the proceeds of a Ramlow fete held recently at the Huntingdon Valley Country Club.

Harvard University \$100,000 for the study of methods to reform and cure criminals and mental defectives by surgery, by the will of J. Ewing Mears.

Army Medical Museum Wishes Material for Study of Pathology of Toxic Gases.—The acute lesions caused by the toxic gases used in the late war have been exhaustively studied, both in man and in animals. Very little definite information is available in regard to the permanent changes caused in the respiratory tract and elsewhere, and this can only be obtained by the study of cases dying either as a late result of the gassing or from some incidental disease. The Surgeon-General requests the cooperation of pathologists in civilian hospitals, who may have occasion to perform necropsies on discharged soldiers giving a definite history of previous gassing. Protocols, clinical histories, gross, and microscopic tissues will be gratefully received. Blocks should be taken from trachea, large bronchi, and other portions of the respiratory tract; from all scarred and pigmented skin lesions; and from all the principal viscera. Fixation in Zenker's without acetic acid or in neutral formalin is preferred. The material will be used in the comprehensive study of the "Pathology of the Toxic Gases" which is now under way. Due acknowledgment will be made as to the source of the material, which should be addressed to the Army Medical Museum, Washington, D. C.

Bills for a National Department of Health.—Two bills have been introduced in Congress providing for a national department of health. S. 814, introduced by Senator Owen, closely resembles the last "Owen bill." It provides for a department and a secretary of health; for an assistant known as the commissioner of health, both to be appointed by the President; for the transfer to the Department of Health of the Public Health Service from the Treasury Department; the Bureau of Chemistry from the Department of Agriculture so

far as it is charged with the investigation of adulteration and the enforcement of the pure food law; and of the Division of Vital Statistics of the Bureau of the Census from the Department of Commerce. The President is also authorized to transfer by executive order any bureau, division or branch of the government engaged in public health work except the Medical Department of the Army and the Bureau of Medicine and Surgery of the Navy. The following bureaus are provided: Sanitary Research, Child Hygiene, Vital Statistics, Foods and Drugs, Quarantine, Sanitary Engineering, Government Hospitals, Personnel and Accounts. An advisory board of seven expert consultants and an official conference of state and territorial health authorities are also authorized. H. R. 5724, introduced by Mr. MacDuffie of Alabama, is similar to S. 814 in its general provisions. It does not specify the bureaus that are to be transferred but leaves this subject to executive order. Instead of a general appropriation, section 10 of this bill appropriates ten million dollars annually: one million for cooperation with the states in establishing a homogeneous system of health administration and for the organization of permanent health agencies in each county; two million for cooperation with the states in sanitation, each state to be allotted an amount proportionate to its area and population; five million for cooperation with the states in control of communicable diseases, and two million for scientific study of the causes and nature of transmission of disease, laboratory research and other investigations. S. 814 has been referred to the Senate Committee on Public Health and National Quarantine, H. R. 5724 to the Committee on Interstate and Foreign Commerce.

National Information Bureau to Pass on Charities.—An organization intended to become the national center of all responsible charities; to cooperate with and, in some sense, to direct them, and to protect the public from imposition has been evolved from the National Investigation Bureau, organized during the war to obtain information regarding war charities. It is called the National Information Bureau, and its aims are to assist in the conservation and proper distribution of the charitable resources of the country and to serve as an endorsement agency for philanthropic organizations, as well as to protect the giving public. Part of its work will be to adapt the programs of the separate organizations to each other and to the communities in which they are engaged, in order to promote the highest efficiency and avoid duplication of effort.

To receive the endorsement of the national agency, charitable organizations must conform to rather rigid standards which it sets up. The agency will be composed of social workers representing the organizations which meet the standards, some of which are:

There must be

1. An active and responsible governing body holding regular meetings, or other satisfactory form of administrative control.
 2. A necessary purpose with no avoidable duplication of the work of another efficiently managed organization.
 3. Complete annual audited accounts prepared by a certified public accountant, showing receipts and disbursements classified and itemized in detail.
 4. No solicitors on commission or other commission methods of raising money.
 5. Ethical methods of publicity, promotion and solicitation of funds.
- There are five other similar standards and additional ones are being devised.

Allen T. Burns, New York, secretary, and Barry C. Smith, New York, director. Gustavus D. Pope, Detroit, has been chosen president. Among the social agencies represented in the organization are: American Red Cross, War Camp Community Service, American Civic Association, National Child Welfare Association, The Charity Organization Society of New York, National Tuberculosis Association, American Social Hygiene Association, New York School of Social Work, National Child Labor Committee, National Association for the Advancement of Colored People, American Society for the Control of Cancer, Cincinnati Council of Social Agencies, Detroit Patriotic Fund, National Municipal League, Cleveland War Council, American Association for Organizing Family Social Work, and the Young Men's Christian Association.

Appropriations for the U. S. Public Health Service.—The Public Health Service has been granted the following appropriations in the Sundry Civil Bill which has passed Congress: for pay, allowance and quarters of commissioned medical officers, \$850,000; for pay of noncommissioned medical officers, \$300,000; for pay of all other employees, \$700,000; for traveling expenses of officers officially detailed to attend meetings

to promote public health, \$40,000; for light, fuel and water, \$125,000; for furniture and repairs, \$8,000; for medical and hospital supplies, \$85,000; for maintaining the Hygienic Laboratory, \$27,000; for the maintenance of Marine hospitals, \$625,000; for medical examination of all persons so entitled, \$220,000; for shipment of bodies \$5,000; for scientific books, \$500; for medical, surgical and hospital services for all persons entitled to treatment under the provisions of the War Risk Insurance Act, \$4,000,000; for the maintenance of quarantine service, \$20,000; for the prevention of epidemics of cholera, typhus fever, yellow fever, smallpox, bubonic plague, Chinese plague, trachoma, influenza or infantile paralysis to be spent in the discretion of the President, in any threatened or actual emergency, \$400,000; for field investigation of the propagation and spread of disease, \$300,000; for interstate quarantine service, \$25,000; for special study and demonstration in rural sanitation, \$50,000; for special study in pellagra, \$30,000; to regulate the sale of biologic products, \$35,000; for the maintenance of the bureau of venereal disease, \$200,000; for the improvement of the Hygienic Laboratory, \$20,000. Regarding the consolidation of the public health bureaus of the government the bill, as finally enacted, contained the following provision: "The heads of the several executive departments and other government establishments are authorized and directed to submit to Congress not later than the first Monday in December, 1919, a statement showing for the fiscal year of 1919 the activities of their respective establishments pertaining to the public health and the amount expended on account of each of the said activities." This language was agreed to after much discussion and is believed to be the first step on the part of Congress toward the eventual establishment of a department of health of the federal government similar in scope to the other executive bureaus of the government. Improvements for Marine hospitals are included, as follows: at Chicago, \$121,000; at Cincinnati, \$10,000; at Mobile, Ala., \$60,000; at Savannah, Ga., \$10,000. The medical department of the Army was granted the following appropriations: for artificial limbs, \$50,000; for appliances for disabled soldiers not entitled to artificial limbs or trusses, \$1,000; for trusses for disabled soldiers, \$1,500; for improvement of the Providence Hospital, Washington, D. C., \$2,000. An effort on the part of the Senate to appropriate about \$2,500,000 for use by the Interdepartmental Hygiene Board to protect citizens against venereal disease failed. The money appropriated at the last session of Congress for this and which remains unexpended was reappropriated for this purpose.

The Physician Under Prohibition.—The inauguration of prohibition throughout the United States affects the physician not only as a citizen, but also as a professional man. Necessarily, the law provides some exceptions, in the use of alcohol and various liquors containing alcohol for medicinal purposes. In a circular of instruction to internal revenue collectors and agents the Commissioner of Internal Revenue states that Section 1 of the Act of Nov. 21, 1918 (War Prohibition Law), provides that after June 30, 1919, until demobilization is proclaimed by the President, no distilled spirits, beer, wine or other intoxicating or vinous liquors shall be sold for beverage purposes. It also provides that the commissioner shall prescribe regulations for the sale of distilled spirits for sacramental, medicinal and other than beverage purposes. The commissioner directs that physicians may prescribe wines and liquors for internal use or alcohol for external use as stated last week. Such prescriptions must be in duplicate, both copies signed in the physician's handwriting. Not more than 1 quart of any liquor may be prescribed for a single patient at a given time and in no case shall a physician prescribe alcoholic liquor unless the patient is under his constant personal supervision. Prescriptions must show the name and address of the patient, including the street or apartment number, if any, the date when the prescription was written, the condition or illness for which prescribed and the name of the pharmacist to whom the prescription is to be presented for filling. Physicians should note carefully this provision: The prescription must designate a certain pharmacist and no other pharmacist can fill the prescription than the one designated. The physician must keep a record in which a separate page is allotted to each patient for whom alcoholic liquors are prescribed and must enter thereon, under the patient's name and address, the date of each prescription, the amount and kind of liquors dispensed by such prescription and the name of the pharmacist filling it. Licensed pharmacists or druggists may fill such prescriptions, provided the druggist's name appears on the prescription in the physician's handwriting

and provided the druggist has received a permit (Form 737), and provided he has qualified as a retail liquor dealer by the payment of a special tax. No prescriptions for alcohol or alcoholic liquors may be refilled. Druggists filling such prescriptions must preserve, in a separate file, one copy of each prescription filled and once a month must send to the collector of internal revenue in the district in which they are located a list showing the names of physicians prescribing alcohol or alcoholic liquors, the names of the patients and the total quantity dispensed to each patient during the month. If these reports show that a physician is prescribing more than normal quantity or that any patient, through the prescriptions of one or more physicians, is procuring more than the normal quantity, the facts shall be reported to the Commissioner of Internal Revenue and the United States Attorney. Pharmacists are instructed to refuse to fill prescriptions if they have reason to believe that physicians are dispensing for other than strictly legitimate medicinal uses or that a patient is securing, through one or more physicians, quantities in excess of the amount required for legitimate purposes. If the prescription is medicated or denatured so as to be unfit for internal use, no beverage alcohol tax paid at the rate of \$2.20 per gallon may be used in filling the prescription, but if it is not so medicated or denatured, liquor tax paid at the rate of \$0.40 per gallon must be used. Physicians preparing or dispensing their own medicines or desiring alcohol for strictly scientific and medicinal purposes must file an application for a permit with the collector of internal revenue of the district in which they live. This application must be accompanied by a bond furnished by a surety company or signed by two individuals as sureties. Both the application and the bond must be in duplicate. On receipt of the application and bond, the collector of internal revenue will issue a permit to the physician authorizing him to have on hand or in transit a certain amount of alcohol or alcoholic liquors, the amount depending on the size of the bond. A bond for \$100 allows the physician to have on hand or in transit 20 gallons of alcohol or liquors. The physician must keep an account of all alcohol or alcoholic liquors purchased and on hand and must be ready at any time to produce his records and satisfy the internal revenue inspectors that any amount used has been for legitimate, medicinal, scientific and nonbeverage purposes. Alcohol or alcoholic liquors purchased by a physician under these circumstances cannot be used for his own consumption. The instructions of the Commissioner of Internal Revenue to all government officers is that the law and the regulations regarding alcohol and alcoholic beverages must be strictly enforced. Physicians should familiarize themselves with the instructions under the law and should carefully and rigidly comply with all requirements. In case of doubt, it is best to secure a ruling or an opinion from the collector of internal revenue rather than to take any risk of violating the law.

FOREIGN

Rabies in Spain.—The *Medicina Ibera* states that an actual epidemic of rabies is prevailing at Seville, and the authorities have started a vigorous campaign against it.

Hospital Train Attacked.—A band of seventy bandits attacked a train, which included American hospital and mail cars, north of Vladivostok, June 11. None of the Americans was injured.

Deaths from Influenza.—According to reports issued by Major Norton Which, sanitary commissioner of India, six million deaths from influenza occurred last year in that country. The deaths from influenza reached a higher proportion in the British troops than in the natives.

Honors for Ruggi.—Prof. G. Ruggi, having reached the age limit of 70 and concluding his forty-fifth year in the chair of surgery at the University of Bologna, has retired. His final lecture is said to have been the scene of an impressive demonstration of affection from his aids and pupils.

Carnegie Medal to Italian Physician.—The *Policlinico* mentions that a Carnegie silver medal for civilian heroism has been conferred on Dr. O. Calamita for his rescue of a soldier from drowning in a canal. He is a member of the medical corps of the army, but the rescue was under circumstances that placed it in the civilian class.

Italian Physician Penalized.—A special *Tribunal militare* has been held at Rome to pass judgment on Dr. Pro who was accused of aiding in the mutilation of certain soldiers to escape military duty. The prosecutor asked a sentence of fifteen years in the penitentiary but partial mental unsound-

ness was accepted as extenuating the guilt of Dr. Pro, and the sentence of six years' imprisonment was imposed. The soldiers involved were given sentences of from ten months to three years.

Central Control Office for Drugs, Etc., in France.—Under the auspices of the ministère du Commerce, a national commission has been founded at Paris, avenue Constant-Coquelin 6, to centralize the control of the supplies of drugs, pharmaceuticals and perfumery. This body plans to study the technical and economic aspect, encourage national production, organize missions, give subsidies to laboratories, and found technical institutes. It has been organized for a five-year period, and the *Paris Médical* says that its budget will not be less than 200,000 francs.

Typhus in Italy.—The *Riforma Medica* states that a few foci of typhus developed last April in Tuscany, Veneto and Campania, and vigorous measures have been taken to prevent the spread of the disease to civilians. The Public Health Service has organized a course of graduate lectures on typhus to train physicians to recognize and treat it. The course is in charge of Professor Lustig of the University of Rome, assisted by three physicians from Trieste who have had much experience with typhus in the various Austrian, Russian, Serbian and Roumanian sectors.

Deaths in the Profession Abroad.—Dr. E. A. Tscherning, professor of surgery at the University of Copenhagen, aged 67. —The *Nederlandsch Tijdschrift* mentions the death of Dr. H. Oppenheim, professor of neurology at the University of Berlin, aged 61. Also the death of Dr. Adolph, professor of obstetrics at the University of Dorpat, Russia, who committed suicide at Konigsberg recently. —The *Paris Médical* reports the death of Dr. Duguay of Lorient who was at the head of a volunteer French hospital unit that had gone to Roumania. He was killed by the bolsheviks.

Prize Awarded Schiøtz and Holth.—At the recent annual meeting of the Norwegian Association for the Advancement of Science, the Videnskabselskab, it was announced that the Fridthjof Nansen prize had been awarded jointly to Professor Schiøtz and Dr. Holth for their work on cataract. In commenting on this, the *Hospitalstidende* expatiates on the importance of the research of these scientists, saying that Schiøtz's tonometer is used now by ophthalmologists almost everywhere for the diagnosis and control of treatment of cataract. Holth also was the first to use the filtering area method, iridocleisis, in treatment of glaucoma.

Prize Awarded in Memory of Bang.—The Gluckstadt prize was founded in 1918 for the most important contribution to the medical sciences by some Scandinavian scientists, and more particularly in the line of diabetes mellitus. It was universally recognized that the most suitable recipient for its first award was Prof. Ivar Bang, of the University of Lund, for his research on the micromethod of determination of the sugar content of the blood. He died, however, just before the date of the awarding of the prize. Not willing to give up this tribute to Professor Bang, the committee in charge of the prize offered it to the University of Lund to give to those who stood closest to Professor Bang in his research. The university has therefore divided the prize between Profs. Karl Petren and Klerker.

Prophylaxis of Venereal Disease in Germany.—The *Nederlandsch Tijdschrift* states that the new German legislation on the prophylaxis of venereal diseases requires the physician to inform the patient or the parent or guardian, if a minor, of the nature and dangers of the transmissible venereal disease which he may discover even when examining or being consulted by the patient for other reasons. A German legal authority is cited to the effect that he is liable for damages in case the person with the venereal disease is not informed of its dangers and thus omits proper treatment or transmits the disease to others. However, he adds, there is no legal obligation on the physician if there is only presumption of a venereal disease.

Reception to Visiting American Commission at Bordeaux.—The *Journal de Médecine de Bordeaux* reports the reception of the Mission américaine de rapprochement économique, intellectuel et artistique at the Medical Faculty. The rector of the University of Bordeaux presided, and expressed his surprise and gratification to see that so many university professors formed part of a partially commercial commission of the kind. Prof. H. W. Tow of the chair of romance languages at the University of Columbia replied that he had had "among his pupils, at Princeton, President Wilson as well as Baker, the chief of the war department, and Hoover,

the present international food commissioner." A *champane d'honneur* was served, and the party inspected the Colonial Museum, the pride of the Medical Faculty.

Belgian Society for Gynecology and Obstetrics.—After an intermission of nearly five years, the Société belge de gynécologie et d'obstétrique held a meeting recently at Brussels. Professor Keiffer recalled that at the twenty-fifth anniversary meeting of the society, March 7, 1914, a number of honorary members were elected, nineteen from Germany or Austria, and seven corresponding members—all names prominent in gynecology and obstetrics. The society at the recent meeting voted unanimously to drop the German and Austrian members, as also a few Belgian members of the society who have compromised themselves by unjustified relations with the enemy. Professor Keiffer said of the latter: "We will exclude them from our ranks and nail them to the pillory." The officers elected by the society for the coming two years are Dr. M. Brouha, president; Dr. J. Godart, vice president, and Dr. M. Cheval, secretary.

Official Visiting Nurses in Bavaria.—The *Nederlandsch Tijdschrift* describes a system of visiting nurses now installed in twenty districts in Bavaria. The women wear a uniform and are bound to professional secrecy, and travel over their district doing welfare work in general, with supervision over pregnant women, midwives, infants, young children and the tuberculous. They have official authority to enforce their advice and to provide ways and means. They are in touch with physicians, clergymen, teachers and state officials in general, aiming at concerted and official welfare work for the public health. They are paid by the district authorities, through the district health officer, to whom they report. Instead of the families seeking advice for their children, tuberculous, etc., in different quarters, the advice is brought to them and there is official supervision to see that they follow it. Our exchange credits the original description of this innovation to the *Wiener klinische Wochenschrift*.

LATIN AMERICA

Hospital Burns.—June 10, a hospital adjacent to the Peter Second docks, Rio de Janeiro was burned. There were several fatalities.

Yellow Fever Spreads.—Dispatches received from Rio de Janeiro tell of the serious situation as regards yellow fever in the vicinity of Bahia.

Hookworm Disease in Panama.—According to the report of Dr. F. A. Miller, the representative of the Rockefeller Foundation in Panama, since the study and treatment of hookworm disease was begun in that country up to last December, there have been examined 86,525 persons, of whom 68,768 received treatment.

Death of Dr. Zayas.—Dr. Francisco Zayas y Jiménez, one of the most prominent Cuban physicians of last century, died, last May, at his home at El Vedado, Cuba, at the age of 93 years. Dr. Zayas practiced his profession for more than fifty years at Havana. He was a well known writer and a poet of note. He also took an active part in politics, being one of the members of the cabinet which was organized by Spain in the last days of its rule in Cuba. He also devoted much attention to the progress of agriculture, and his studies on tobacco and sugar planting attracted much attention.

University Interchanges.—The *Crónica Médico-Quirúrgica* of Havana for March relates that Dr. Schofield, professor of comparative literature at Harvard University, has been visiting Cuba in the interests of university interchanges of professors and students between Harvard University and the University of Havana. The Cuban educational authority, the secretario de instrucción pública y bellas artes, has accepted the plan and has made arrangements for the proposed interchange of both professors and students. Our exchange adds: "Es de aplaudir esta actitud en pro del intercambio cultural norteamericano con nuestra clase universitaria."

Prize Awarded to Arteaga.—At the recent anniversary meeting of the Academia de Ciencias de la Habana, the Gordon y Acosta prize was awarded to Dr. J. F. Arteaga for his work on the physiology of hunger and thirst. Dr. Arteaga is the editor in chief of the *Revista de Medicina y Cirugía* of Havana. Three prizes are offered for the coming year for the best works on the glands with an internal secretion, a plan for a campaign against malaria in Cuba, and the third prize for any theme the writer may select. The competing works must be unpublished, written in Spanish, English or French, with name in sealed envelop, and they must reach

the secretary of the Academy, calle de Cuba 84 A, before March 31, 1920.

Maternity Prizes in Cuba.—The *Crónica Médico-Quirúrgica* of Havana states that the work initiated by the late Dr. E. Núñez in providing prizes for motherhood has taken a firm foothold in Cuba. This year forty-one of the total 112 municipalities of the island are now offering prizes of the kind in the campaign for better babies. The movement is widespread through the island, each of the six provinces having a representative proportion of prizes to be awarded. The total amount thus available in the different towns ranges from \$25 to \$305, except at Havana where the total of the prizes to be awarded reaches \$1,500. In addition to these local prizes, a number are to be awarded by the public health authorities and by private philanthropists.

Personal.—Dr. Justo F. González of Uruguay has just arrived in this country, having been commissioned by his government to study the etiology and serotherapy of influenza and to purchase some apparatus for the disinfection of water and the disinfection of ships. Dr. González expects to visit the cities of New York, Washington, Boston, Philadelphia and Rochester, Minn. Mrs. González, who accompanies him, is the president of the National Public Health Association of Uruguay. Dr. de Paulo Sousa, São Paulo, Brazil, professor of hygiene and public health of the University of Brazil, and head of the public health department of São Paulo, arrived in Norfolk, Va., June 22, to make a study of the methods of health departments of American cities.

Monument to Medical Patriots in Colombia.—The *Repertorio de Medicina y Cirugía* of Bogotá publishes a circular inaugurating a movement in favor of a memorial for the members of the profession "who left their homes and practices a hundred years ago to aid in the campaign for the independence of the country, so gloriously won at the battle of Boyacá, the centennial celebration of which is at hand." The circular is signed by the presiding officer of the Academia Nacional de Medicina, of the Facultad de Medicina de Bogotá, the Sociedad de Cirugía de Bogotá, the Club Médico de Bogotá, the Sociedad de Pediatría de Bogotá and the Sociedad de Medicina de Bogotá. There is a general movement throughout the country to honor the memory of the patriots who founded the republic, and the medical profession is planning a monument to be erected in the principal court of the Bogotá Medical School. The circular adds, "The monument will be modest and materially small, but it will be grandiose in the ideas which it incarnates and symbolizes. It is to be constructed with funds contributed by the physicians of Colombia in tribute to the devotion, the self-abnegation and the patriotism of those physicians who gave their science and best services to maintain the health of the troops who fought on the glorious fields of Boyacá, Carabobo and a thousand others, establishing the independence of the five Bolivian republics."

LONDON LETTER

LONDON, June 18, 1919.

British-American Discussion on Pediatrics

The presence of a large number of medical officers from the United States and the British dominions in this country has been turned to account by holding various conferences in which these countries have been represented. The latest is an informal conference on pediatrics held by the Local Government Board and presided over by the chief medical officer, Sir George Newman. The members of the conference consisted entirely of experts: Col. J. G. Adams, F.R.S., F.R.C.P. (professor of pathology, McGill University, Montreal); Capt. Richard A. Bolt (chief, Bureau of Child Hygiene, Cleveland); Hector C. Cameron (physician in charge of the Children's Department, Guy's Hospital); Miss Janet Mary Campbell, M.D., M.S. (medical officer in charge of maternity and child welfare, Local Government Board); John S. Fairbairn (obstetric physician to St. Thomas' Hospital and General Lying-In Hospital, lecturer in midwifery and diseases of women, St. Thomas' Hospital Medical School); Eardley Holland (assistant obstetric physician to the London Hospital); F. Truby King (general President, Royal New Zealand Society for the Health of Women and Children); Miss Janet E. Lane-Claydon (dean and lecturer in hygiene, Household and Social Science Department, King's College for Women, London); G. F. C. Pritchard (physician, Queen's Hospital for Children; physician, City of London Hospital for Diseases of the Chest); W. R. Ramsey (associate professor of diseases of children, University of Minne-

sota Medical School); Lieut.-Col. G. S. Strathy (assistant physician, Hospital for Sick Children, Toronto), and S. W. Wheaton (assistant medical officer, Local Government Board).

Prof. W. R. Ramsey said that since there had been a special department of pediatrics at the University of Minnesota Medical School, progress had been rapid. Intensive teaching of pediatrics in close cooperation with obstetrics was necessary and was there carried out. The average physician approached the child from the pathologic standpoint. He was interested whether the child had pneumonia, a dilated heart, a big liver, or some other abnormal condition. But the normal infant was the most important thing to teach the student. The welfare of the race depended fundamentally on prenatal care, breast feeding, and the technique brought to bear in the first years of life. Nothing in the whole field of medicine required more judgment, more experience, and a more thorough analysis than the feeding of infants. A few years ago they had got down in America to such a position that probably not more than 30 or 40 per cent. of the women were nursing their children. Now the percentage was between 75 and 80. The improvement was brought about by propaganda and the proper education of the physician and nurse. But a great deal more remained to be done. The average physician of today thought that the baby must be bathed immediately after birth. The result was exposure for half an hour or more in a room of low temperature, with many deaths as the result of loss of heat. It was a common practice to wash or swab out the baby's mouth daily, producing stomatitis. The epithelium was brushed off and thrush followed. A large percentage of the dyspepsia in young infants was due to the classic dose of castor oil on the third day. He advocated four-hourly feeding and only five feedings in the twenty-four hours. This gave much better results than more frequent feeding. The frequent feeding of young babies and the waking of the mothers at night was the reason a great many infants were not breast fed; the mother became nervous, lost her sleep, and her milk gradually disappeared. At Minnesota they found that Rubner's and Heubner's allowance of 100 calories per kilogram was not applicable to the first two weeks. Infants gained most satisfactorily on from 45 to 70 calories per kilogram.

Dr. Truby King said that the common mistake was irregularity and undue frequency in feeding. The main damage to the baby often originated in the first fortnight in life. He agreed with Dr. Ramsey's conclusion that the average quantity of mother's milk on which the baby thrived at 10 days of age was only about 13 ounces and not the German standard of 18 ounces so largely followed. The former figure was also arrived at in Paris by Professor Marfan.

Dr. H. C. Cameron said that the curriculum of the medical student was overcrowded, but that three months' study should be given to pediatrics, which was not a narrow specialty but formed the formation of almost all that the student learned elsewhere. Too much time was given to the study of anatomy, which was soon forgotten, and to surgical procedures which were really objects for postgraduate study and were a narrow specialty. Few students—only the best with the keenest intellects—threw themselves heart and soul into the study of the individual child. It was much easier for the student to be keen on the removal of adenoids than to understand how they came and could be prevented.

The conference unanimously adopted these conclusions: 1. Every effort should be made to impress on the whole community the supreme importance of breast-feeding, for the sake of both mother and child; at present overfeeding of the baby, especially in the first fortnight of life, is one of the commonest and most serious mistakes of nursing mothers, often upsetting the child and leading to the early abandonment of suckling. 2. This tendency can be best counteracted by a general recognition of the benefit of greater regularity and lessened frequency of feeding than is customary. 3. With very few exceptions, nursing only every four hours from birth is best for mother and child, though in a few cases more frequent feeding may be desirable. 4. In general, there should be an interval of seven or eight hours between the last feeding at night and the first feeding in the morning. 5. Every medical student preparing for a registrable qualification shall receive adequate teaching in the subjects of infancy and childhood in health and disease; attendance in a department where instruction is given in these subjects should be compulsory for a period of not less than three months; some special part of the final examination in medicine should be devoted to these subjects. 6. So far as practicable, this study shall follow on, and be coordinated with, a satisfactory course in obstetrics and gynecology, and should

be made available for postgraduate students; the present training in obstetrics leaves much to be desired, especially in regard to the lack of facilities for bedside teaching in midwifery. 7. Great advantage would result from a larger measure of uniformity in the advice given by public authorities and others in respect of maternity, infant and child welfare. The only way in which this can be secured is by obtaining a written statement from a body of experts. 8. Both practical and theoretical instruction in infant hygiene should form a part of the training of midwives and of all persons engaged by public authorities in infant welfare work. 9. Maternity nursing should be undertaken only by competent and adequately trained persons, preferably by qualified midwives.

Infant Mortality and Fresh Air

At the National Birth Rate Commission, Prof. Leonard Hill gave evidence which consisted largely in the application of his well-known views on ventilation and fresh air to infant mortality. He said that the high mortality of children was due to excess of respiratory and alimentary diseases, particularly of the latter. The cooling and evaporative powers of the air were closely connected with the causes of high infant mortality, these acting both on the skin and on the respiratory membrane. Cool morning air was the natural stimulus to activity and appetite, to deep breathing, active circulation, thorough oxygenation, and good digestion. Physiologic research had proved that, apart from the spread of infection by "carriers," it was not the chemical impurity, but the physical conditions of close air which made for discomfort and impoverished health. It was not excess of carbon dioxide, or lack of oxygen, or organic impurities which affected people in a crowded room, but the heat and moisture of the air. The cooling and evaporative powers in rooms commonly approximated to those in tropical humid climates, so admittedly enervating to man. This was due chiefly to the stillness of the atmosphere. Exposure to wind had a most potent influence on the cooling and evaporative powers. Open-air workers and agriculturists, fishermen, and the like, were exposed to a greater cooling and evaporative power than citizens who dwell in tenements, traveled in crowded conveyances, worked in schoolrooms or factories, ate in canteens, and sought amusement in cinemas. It was the lack of windage which largely explained the correlation between density of population and high morbidity and mortality. The tenement baby, overclothed and confined indoors by the mother—for fear of its catching cold and to save trouble under the difficulties of tenement life—died from digestive, nutritive and respiratory troubles, brought on largely by lack of adequate cooling and evaporative powers of air. It was surrounded with a tropical, still, humid atmosphere.

The depression of metabolism and the want of fresh natural foods, grass-fed milk and butter, succulent fresh young garden produce, alike resulted from the present city conditions, and these together were the causes of "deficiency" diseases, such as scurvy and rickets, with the decay of teeth, and an enormous amount of ill health, which was not actually identified as disease. Garden cities which were built and big towns not added to. The government should choose new sites with beautiful surroundings and with all the conditions that favor a happy and healthy life. The whole question should be gone into as boldly and as thoroughly as the war had been faced. That was the only way to get better conditions, and it was the one way to escape the perils which had overtaken Russia. An immediate and pressing demand should be made for garden cities and the bringing up of the young in the discipline of taking pride in and keeping perfect bodily health. The present system of national education weakened the vigor and lessened the happiness of the nation. All children should receive the education that public school boys obtain on the playing field.

The Chronicity of Dysentery Infection

An important investigation of chronicity in dysentery carriers has been made for the Medical Research Committee by Capt. W. Fletcher and Dr. Doris Mackinnon. Advantage has been taken of the large number of cases in soldiers returning from foreign service suffering or convalescent from the disease who have been collected together in special hospitals. In regard to amebic dysentery the well-known chronicity was confirmed by cases which date back fifteen or twenty years. But it is with regard to bacillary dysentery, the chronicity of which has been little recognized, that the research is more important. During the examination of 1,782 men convalescent from dysentery, seventy-four bacillus carriers and 122 carriers of *Endanella histolytica* were found.

Further, forty-two convalescents whose examinations proved negative showed a history of chronic disease (diarrhea, and melena from time to time) similar to that obtaining among those with positive examinations. An important clinical differentiation between the carriers of the Flexner and Shiga bacilli was established. "The average Flexner carrier is in good health; his stools are formed and free from blood and mucus if his intestine has not been damaged by inflammation due to amebiasis or some other cause. He is fit to carry on his work unless he is subjected to very adverse conditions of feeding, temperature or labor, which may induce attacks of diarrhea. The Shiga carrier, on the other hand, is generally an invalid; his stools usually contain blood and mucus, and he has frequent attacks of diarrhea. But this is not all; for in addition to his bodily ailments he often becomes a mental wreck. The weakening effect of the constant diarrhea, the straining and tenesmus, the dragging sensation in the abdomen, the concentration of the attention on the presence or absence of blood and slime in the stools, and the frequent disappointment, due to repeated relapses, tell on the patient's mind and reduce his mental state to one of misery and dejection." Infections with Shiga's bacillus are found to be contracted in the East; are liable to last months or even years, defying every effort at cure, and are prone to relapse on any departure from a quiet semi-invalid life or plain light diet. Cases are quoted giving an estimated duration of infection over periods varying from two to ten years. The intermission of the Flexner infection, comparatively good health of the subject, and normal appearance of the stools render the carrier a dangerous source of the disease. Captain Fletcher and Dr. Mackinnon recommend that the examination of dysentery convalescents should be carried out in laboratories attached to the hospitals so that the laboratory worker can deal directly with the patient and direct the medical attendant. Chronic Flexner bacillus carriers should be employed for six months in light occupations, not concerned in the handling of food, and then sent to the hospital for two weeks, during which their stools should be examined at least six times. Chronic Shiga bacillus carriers should after discharge from the army be placed under the supervision of the health authorities. A permanent depot should be established for those chronic cases which resist all treatment.

Trade Unionism in the Profession

The fifth annual meeting of the Medicopolitical Union has been held. It was stated that 367 new members have joined during the last month. The report of the general secretary regretted the hostility which had sprung up between the British Medical Association and the union. The report proceeded: "The association had for many years, while decrying trade unionism, been employing trade-union methods with impunity, until the Coventry case (previously reported in THE JOURNAL) shattered their claims and left us as the only body adequately equipped to carry on a fight on behalf of the profession. I am pleased to say that the association, or certain of its members, recognize facts, and an attempt is now being made to reconcile differences." As to the formation of a ministry of health, the report stated that it foreshadowed drastic changes in the medical services at an early date. Those changes would benefit neither the community nor the profession, unless the latter had a large voice in shaping them. It was the duty of that union to impress on the government departments the importance of the general practitioner as the backbone in the medical profession, and the fact that he was better equipped to give advice than those occupying a more exalted position.

The Law and Professional Secrecy

In this country the law has never recognized the inviolability of professional secrets in the keeping of the medical profession, as it does on the European continent. Curiously, there is no question as to the inviolability of the secrets of the Roman Catholic confessional. However, the rule on the point is somewhat obscure, and is contested, as the following case shows: A girl was charged with concealment of birth. A physician was called when she was prostrate after she had placed the body of the baby under the mattress. The judge remarked that in his depositions the physician stated that though he knew a child had been born he did not think it his duty to inform the police, as that would have been a breach of professional confidence. The judge remarked that there was no professional confidence in criminal cases, and it was the physician's duty to inform the police. He did not blame the physician for his view, but he thought that he should know that his view was wrong. The physician said that he was informed by the British Medical Association that he was

correct. The judge said that the British Medical Association was wrong. If a patient cut another person's throat it would be his duty to inform the police. There was no difference between these cases.

PARIS LETTER

PARIS, June 20, 1919.

The Compulsory Reporting of Tuberculosis

At the session held, June 3, by the Academy of Medicine, the permanent commission on tuberculosis adopted unanimously the following conclusions in regard to making tuberculosis a reportable disease, in addition to those reported in *THE JOURNAL*, June 14, 1919, p. 1781: The academy congratulates the government on its intention of giving new impulse to the antituberculosis campaign, which has made so much progress in the last few years. The academy indorses the measures now in force and hopes that they will be multiplied so that they may be extended to the whole country. In the opinion of the academy it seems necessary to coordinate all these measures by placing them under some sort of central office. In order to supplement the means now employed, as represented by dispensaries, sanatoriums, special hospitals and farm colonies, the academy requests that the measures for the conservation of infants now in force in the department of the Seine be extended to the different départements of France. The academy invites the attention of the government to the importance of public health regulations relating to abattoirs, stables and the protection of food against street dust and insects. The conduct of antituberculosis work, and in a general way the enforcement of laws on social hygiene, will require the employment of many physicians with public health training. As the teaching of hygiene is inadequate in France, the academy reiterates the recommendation it made when the question of depopulation was discussed in 1917. It desires the creation of one or more national institutions of public health having for their purpose the promotion of this important science and the formation of sanitarians. In order to hasten the carrying out of the measures for relief and prophylaxis, the academy insists on the importance of encouraging by all means the conduct of antituberculosis work by private initiative, in addition to the measures taken by the different governmental agencies.

Work of a Society for the Assistance of War Cripples

The Aide immédiate aux invalides et réformés de la guerre, the object of which is to insure the permanent care of the war cripples by assisting them by means of reeducation, hospitalization and finding them new positions, has just taken possession of its new offices. On this occasion some inaugural ceremonies took place, presided over by M. Colliard, minister of labor and social prevention, assisted by M. Paul Deschanel, president of the chamber of deputies, who is also honorary president of the above mentioned organization. The latter described the results of the work accomplished by the Aide immédiate, which is at present reeducating 1,854 cripples; 1,654 wounded have in addition placed themselves in communication with the association; 9,998 have been assisted; 9,201 have been found employment; 2,092 were referred to the official schools of rehabilitation; 587 tuberculosis cases have been treated at the society sanatorium; 626 families have received some form of permanent assistance; there has been organized a system for placing with families the children of wounded soldiers; in addition there has been formed a club where those rehabilitated can meet together.

At present the Aide immédiate is spending 74,000 francs every month (nearly \$15,000); it is training 281 war disabled to whom it is granting an allowance of 5 francs a day; it is caring for thirty tuberculosis patients at its sanatorium; it is distributing each day milk and meat to 528 war disabled; it is giving some form of monthly assistance to 615 cripples and their families, and it is finding employment for more than 300 cripples every month.

The French Hospital at Athens

M. de Billy, the French minister at Athens, presided recently at the inauguration of the French hospital which has been founded by the French government. There were present members of the Greek government, many professors of the university, members of the French military missions and representatives of the Athenian scientific societies. The French minister delivered an address indicating the purpose of the French government in founding the hospital.

Congratulations to the Red Cross

The president of France has just addressed a letter to Mr. H. P. Davison, the chairman of the governing board of the league of societies of the Red Cross in which he says: "At this moment when your persevering efforts have met with success I want to congratulate you. The statutes adopted by the Red Cross League constitute a deserved tribute to the efforts already made by the international council of the Red Cross in the new field of effort where the governing board desires to engage and making the admission into the league of all Red Cross societies depend on the unanimous decision of the board. I have noted this event with interest and I have no doubt that the organization which you have initiated will perform in the future the generous task assumed by it for the benefit of the people."

Attitude of Paris Medical Society

The syndicat médical de Paris, at its general assembly held under the presidency of Dr. Henry Barlier, one of the hospital physicians, adopted three important resolutions: The first pleads for the obligatory presentation of college diplomas before students are allowed to begin medical studies. The second urges that no license be granted to practice medicine in France to foreign physicians, save under exceptional circumstances and only if they have served in the French army during the war. The third resolution protests against the veiled attacks on the medical profession because of the compulsory reporting of tuberculosis: the medical society of Paris asserts its unchangeable opposition in regard to making tuberculosis a reportable disease while the government does not put into effect a program aiming at the limitation of the consumption of liquor, the strict enforcement of the law on drunkenness, the sanitation of insanitary dwellings, the improvement of the services of public health and disinfection, the construction of numerous sanatoriums, and the passage of laws for compulsory insurance against sickness, and declares itself ready to take up actively all measures that will promote the interests of the patients and of the country as a whole.

Franco-American Celebration

An imposing ceremony took place, May 29, at Beaune, at the commencement exercises at the university, in which 10,000 students belonging to the American army have been taking for the last few months courses organized by the staff of the American army. The French government was represented by M. Lafferre, the minister of education, M. Claville, minister of public works, and M. André Tardieu, high commissioner for French-American war affairs. A large number of French professors and staff officers were also present. At the end of the celebration, M. Lafferre presented a number of Legion of Honor crosses to those Americans who have contributed most to this work of education in the army.

Delegation from English Universities

A delegation from the English universities, which was invited by the national office of the universities of France to visit French universities, arrived, May 30. After being received at the University of Paris, the delegates will leave for an inspection trip of the provincial universities. Some conferences will be held at the office of the university between the English and the French professors in order to reach an agreement as to an exchange of professors and students between the universities of the two countries.

Personal

At one of its last sessions, the Academy of Medicine elected five national corresponding members for the division of surgical pathology and obstetrics. Those elected were Dr. Berard, professor of clinical surgery at the school of medicine of Lyons; Dr. Civelli of Melbourne; Dr. Fabre, professor of clinical obstetrics at the school of medicine of Lyons; Dr. Seneert, professor of clinical surgery at the school of medicine at Strasbourg, and Dr. Vanvets, associate professor of the school of medicine of Lille.

Surgical Treatment of the Scars from War Wounds

At a recent meeting of the Academy of Medicine, Dr. Walther, hospital surgeon and associate professor at the Faculté de médecine de Paris, contributed an interesting communication on the subject of the surgical treatment of the scars from war wounds. Since the beginning of the war, Dr. Walther was in charge of a service especially equipped for the treatment of scars of the soft parts and of nerve

lesions. Before the society he gave a general survey of the conditions which he thinks should obtain in the operative treatment of scars of the limbs. He first emphasized the importance of preoperative treatment by means of gymnastics and special muscle training, which should always be adapted in accordance with the indications and followed out under the supervision of the surgeon. Certain points of the operative technic were brought out, such as very wide resection without excision of the scars; resection of all the deep scars, including the fibrous clumps which surround the muscles, the nerves and the vessels; together with as complete reparation as possible of the muscles and neuroses. He recommends the use, during the whole course of the operation, of a bath of physiologic sodium chlorid solution which prevents the desiccation and alteration of the tissues and through its very powerful hemostatic action facilitates dissection. It is also indicated to proceed, after the operation, to the absolute immobilization of the limb by means of a plaster cast, which should be left in place for at least two weeks, and for four or five weeks when it is a question of repairing the muscles and tendons; nor should a change of dressing be necessary, if the skin sutures have been made with fine catgut. The postoperative treatment by means of gymnastic exercise should be directed and controlled by the surgeon.

The results obtained encourage one to extend the indications for surgical intervention. Walther called attention to the various and numerous troubles which may arise from the presence of deep scars, even though only slightly painful, and to the functional improvement that can be secured even in the case of large scars, with deep and extensive laceration of the tissues, such as are often regarded as ineradicable and entail permanent disability. Many men with wounds of long standing are still suffering from disability and from marked functional inferiority who would benefit from surgical intervention. At the present time, the fact that all the auxiliary hospitals were being discontinued made it difficult to provide hospitalization, and the fear was expressed that many wounded men would remain permanently disabled who might otherwise be benefited. It seemed a matter of urgent necessity to organize surgical centers for the treatment of scars, as has been done for the treatment of face wounds, osteitis, pseudarthrosis, etc. Such centers should be provided with all the equipment needed for preoperative and post-operative treatment.

Dr. Babinski, hospital surgeon in Paris, endorsed the observations made by Walther. Some patients with deep scars were regarded as neuropaths, psychopaths or malingers and sent as such to the neurologic service; whereas the resection of deep scars has always been followed by the cure, or at least the improvement, of such patients.

Drs. Schwartz and Tuffier, associate professors at the Faculté de Médecine de Paris, likewise emphasized the necessity of establishing special centers for men with vicious scars who are in need of operative treatment. Such centers should admit not only the wounded who are still in the service but also those who have been discharged.

A Maternity Dispensary and a Children's Hospital

At one of the recent meetings of the Pediatric Society, Dr. Ramsay, of the University of Minnesota, gave an account of the work done at Rouen and in the department of the Seine-Inférieure by the American Red Cross in collaboration with the prefect of the department.

Dr. Ramsay expressed his opinion to the effect that in each department there should be a central bureau, directed by the state, whose duty it should be to coordinate all welfare endeavors, both public and private. This bureau, which should be at the same time a social center from the standpoint of propaganda and organization, would comprise a dispensary type, a nursery, a children's hospital, etc. It would be directed by a medical committee at the head of which would be the medical director of the bureau of hygiene, who would be assisted by pediatricians and obstetricians. An important rôle would devolve on the visiting nurses, aided by the attending nurses and such as have made a specialty of infant hygiene.

A central dispensary conceived according to this plan is in operation at Rouen, with annexes at Dieppe and at Elbeuf. These dispensaries at present are receiving financial aid from the department authorities, who are desirous of continuing the work undertaken by the American Red Cross.

Concessions to Medical Students

In order that students of medicine and pharmacy belonging to combat units may benefit by the measures that have been taken in favor of their comrades in the medical depart-

ment of the army, as regards permission to continue their studies, the minister of war has just issued an order in accordance with which all students of medicine and pharmacy (with the exception of certain classes actively engaged) who are at the present time mobilized in combat units, who are holders of the P. C. N. diploma (that is to say, who have had one year's training in the premedical subjects of physics, chemistry and general science) and are entitled to two credits in medicine shall be allowed to return to their colleges or universities, July 15, 1919, to complete their studies.

Statistics of Charitable Work

The Office central des oeuvres de bienfaisance recently held its general meeting under the chairmanship of M. Valléry-Radot, president of the administrative council. In the last quarter of a century, the organization has ministered, in one form and another, to the wants of 1,123,932 people. It has distributed either directly or through other organizations the sum of \$3,327,329. Sums that have been recently available have amounted to \$520,000.

Closing of the Franco-Uruguayan Hospital

June 11, the ceremonies in connection with the closing of the Franco-Uruguayan hospital were held in Paris. This hospital was founded and directed by Mme. Gaston Thomson, Dr. Louis Mourier, undersecretary of state for the medical department of the army, presided at the ceremonies, and after thanking Mme. Gaston Thomson and her co-workers for their indefatigable devotion, he presented the insignia of an officer of the Legion of Honor to Dr. Blanco Acevedo, chief surgeon of the hospital.

It may be well to add that this hospital will not actually cease to exist, for all the equipment is to be transported to South America, where it will serve to found a French hospital at Montevideo, which will be under the direction of Dr. Blanco Acevedo.

Decoration of a Nurse with the Legion of Honor

Mme. Guérin de Belleil, a nurse, has just received the cross of an officer of the Legion of Honor with the following citation:

Mme. Guérin, an army nurse of the highest moral worth, since the beginning of the war, has given proof of the most admirable devotion. She was wounded by a shell fragment, March 20, 1918, at the field hospital of Châlons-sur-Vesles; a second time by an aerial bomb, June 2, 1918, at Coulommiers; also gassed, May 28 and 29, during the bombardment of Gueux. Furthermore, she offered herself as a donor of blood for a transfusion. She has already been cited in an army order.

Cultivation and Preparation of Medicinal Plants

In April, 1918, there was created, under the ministry of commerce, a committee whose duty it should be to organize and intensify in France the cultivation, the harvesting and the preparation of medicinal plants (THE JOURNAL, July 13, 1918, p. 130). This committee endeavored to offset, as far as possible, the shortage in France and to supply, with the aid of the resources drawn from the capital, the immediate needs of the French pharmacists. The return to a normal economic state imposes new duties on the committee. It now proposes, in particular, to direct its efforts toward the cultivation and harvesting of plants that are valuable to the perfume industry on account of their essential oils. It desires, at the same time, to study ways and means of reestablishing in France the drug market which the central empires had monopolized. It will also endeavor to develop in our colonial domain the cultivation of medicinal plants which France is at present obliged to secure from foreign countries.

Personal

Dr. Lapeyre, professor of external pathology at the Ecole préparatoire de médecine et de pharmacie de Tours, has been appointed professor of clinical surgery in the same school. Dr. Tillaye, acting professor of pathology, clinical surgery and clinical obstetrics at the same school, has been appointed professor of external pathology.

Dr. Theodore Tuffier, hospital surgeon and agrégé professor at the Faculté de médecine de Paris, has recently received, in an army order, the following citation:

Dr. Theodore Tuffier, a surgeon of the highest distinction, although not drafted and although exempt from all military obligations, has brought to the army, from October, 1914, up to the last day of the war, the cooperation of his medical skill, especially during the great military operations of Champagne, Verdun, the Somme, Flanders, the Aisne and the Marne.

Marriages

WALTER FRANCIS STILLER, Capt., M. C., U. S. Army, New York City, on duty with Base Hospital No. 65, Kerhuon, France, to Mlle. Jeanne Bourgeaud of Doulaincourt, Haute Marne, France, May 27.

IRA VERNON GRISSOM, Lillybrook, W. Va., to Miss Amy Eleanor Hines of Princeton, W. Va., June 25.

MATHIAS ALOYSIUS MCGARTY to Miss Mary Germaine O'Connell, both of La Crosse, Wis., June 10.

SARAH ADAMS BOND to Mr. Frederick A. Fraiser, both of Jamaica Plain, Boston, June 20.

JAMES LOUIS RANSOM, Topeka, Kan., to Miss Jennie Roswell of Salina, Kan., June 30.

JAMES E. CALLAWAY to Mrs. Ethel Kalkins, both of Chillicothe, Mo., June 20.

CHARLES SIXTUS REHFELDT to Miss Emma Fehl, both of St. Louis, June 14.

Deaths

Frederick Gillette Harris * Chicago; University of Illinois, Chicago, 1899; aged 44; died suddenly at his home, July 2, from meningitis. Dr. Harris, who was a native of Chicago, was one of the best known dermatologists of the Northwest. He studied abroad in 1903, 1904, 1907 and 1908, and then became a member of the teaching force of his alma mater, which he served as professor of physical diagnosis, instructor in medicine and associate professor of dermatology until 1912. He was also professor of dermatology and syphilology in the Illinois Post Graduate Medical School and later in the Northwestern University Medical School, Chicago. The latter position he held up to the time of his death.

William Cavan Woolsey * Brooklyn; College of Physicians and Surgeons in the City of New York, 1898; aged 43; surgeon to St. Christopher's and of Kings County hospitals; adjunct in gynecology in the Polhemus Medical Clinic, and consulting anesthetist to the Bushwick Central Hospital; who was honorably discharged, February 13, as major, M. C., U. S. Army, after service with the American Expeditionary Forces in France; died in his apartments in Brooklyn, June 23, from the effects of a gunshot wound, believed to have been self-inflicted, with suicidal intent.

Sarah Adams Bond Fraiser * Boston; Woman's Medical College of Pennsylvania, Philadelphia, 1891; aged 60; for many years a member and senior medical officer of the staff of the New England Hospital for Women; president of the New England Women's Medical Society; died at her home in Jamaica Plain, Boston, June 27, from pneumonia.

John Holmes Smith, Baltimore; University of Pennsylvania, Philadelphia, 1880; aged 62; a member of the Medical and Chirurgial Faculty of Maryland; lecturer on clinical surgery and professor of anatomy in the University of Maryland; died at his home, near Kingsville, Baltimore County, June 21, from cerebral hemorrhage.

George Henry Houghton, Albany, N. Y.; Albany (N. Y.) Medical College, 1882; aged 66; a member of the Medical Society of the State of New York; who entered the Champlain Valley Hospital, Plattsburg, N. Y., about five weeks before, to undergo operation; died in that institution, June 15, from carcinoma of the stomach.

James Herman Betz, Jamaica, N. Y.; Pennsylvania Medical College, Philadelphia; aged 63; also a graduate in pharmacy; for twenty-two years an attaché of the New York Department of Health and for a long time chief sanitary inspector of Queen's Borough; died at his home, April 17.

Andrew V. Cherbonnier, Baltimore; Capt., M. C., U. S. Army (retired); aged 92; who was commissioned captain in the Medical Corps, July 28, 1866, and was retired by operation of law, Oct. 12, 1890, on attaining the age of 64 years; died at his home, June 25, from senile debility.

Silas Murray Dinsmore * Keene, N. H.; Columbian University, Washington, D. C., 1860; aged 83; a member of the staff of the Elliott City Hospital, Keene, and a member of the local school board for twenty-six years; died at his home, May 14, from middle ear infection.

Charles English Henderson, Easton, Md.; University of Pennsylvania, Philadelphia, 1858; aged 74; who entered the railway service in 1870; serving in various capacities, and was for the last thirty years general manager and receiver of railways; died at his home, April 8.

Robert Meade Smith, Norristown, Pa.; University of Pennsylvania, Philadelphia, 1876; aged 65; formerly an instructor in his alma mater; died at his home, June 22, from the effects of a gunshot wound, self-inflicted, it is believed, while dependent on account of ill health.

William Augustus Seymour, Roseland, Mont.; Northwestern University Medical School, Chicago, 1910; aged 39; a member of the Montana Medical Association; was accidentally drowned, May 14, at Vananda, Mont., as the result of an automobile accident.

Robert Wood Fort, Atlanta, Ga.; Emory University, Atlanta, 1886; surgeon of U. S. Volunteers during the Spanish-American War, with service in the Philippine Islands; died suddenly in New York City, June 15.

Robert Eliel Chaffin * Nevada, Iowa; Miami Medical College, Cincinnati, 1893; aged 59; died at his home, May 3, from visceral paralysis following gastro-enterostomy for the relief of hemorrhage from duodenal ulcer.

William Sherman Robinson, Holland, Mo.; Barnes Medical College, St. Louis, 1895; aged 54; a member of the Missouri State Medical Association; died in a hospital near Nashville, Tenn., June 16, from pellagra.

Lionel Maximilian Archambault, Arctic, R. I.; College of Physicians and Surgeons, Baltimore, 1909; aged 32; a member of the Rhode Island Medical Society; died at his former home in Haverhill, Mass., June 5.

Melvin J. Bellinger * Council Bluffs, Iowa; Drake University, Des Moines, Iowa, 1886; aged 55; died in the Jennie Edmondson Memorial Hospital, Council Bluffs, June 24, from carcinoma of the liver.

Joel V. Bastin, Fillmore, Ind.; Kentucky School of Medicine, Louisville, 1887; aged 60; a member of the Indiana State Medical Association; died at his home, June 23, from pneumonia.

Martha Marill Crofut * La Grange, Ill., formerly of Denton, Texas; University of Illinois, Chicago, 1907; aged 59; died in the Ravenswood Hospital, Chicago, July 4, from carcinoma.

Maria Morrison Dean * Helena, Mont.; Boston University, 1883; aged 62; prominent in child welfare activities and the suffrage campaign; died at the home of her sister in Helena, May 23.

John Warren Trimble, Chillicothe, Mo. (license, Missouri, 1883); aged 65; a practitioner since 1872; also a graduate in pharmacy; died at his home, June 6, from carcinoma of the liver.

Thomas Ray Morrison, Churubusco, Ind.; Fort Wayne (Ind.) College of Medicine, 1884; aged 81; a veteran of the Civil War; died at his home, June 21, from uremia.

David S. Speer * Somlake, Texas; Northwestern Medical College, St. Joseph, Mo., 1894; aged 57; died in Huntington, Pa., June 19, from cerebral hemorrhage.

Charles Allen Moore, Fremont, Ind.; Medical College of Ohio, Cincinnati, 1900; aged 48; also a pharmacist; died at his home, June 1, from carcinoma.

Joseph Gardner, Bedford, Ind.; University of Louisville, Ky., 1861; aged 86; died at his home, near Bedford, March 3, from senile debility.

Edward McGrath, Peterborough, Ont.; Queens University, Kingston, Ont., 1888; aged 68; died at his home in March from gastric ulcer.

John M. H. Lennon, Kearsarge, N. H.; Tufts Medical School, Boston, 1911; aged 34; died at his home, June 3, from tuberculosis.

T. Preston Wiseman, Santa Ana, Calif.; College of Physicians and Surgeons, Keokuk, Iowa, 1875; aged 74; died at his home, May 5.

William H. Schrader, Chicago; Hahnemann Medical College, Chicago, 1887; aged 61; died at his home, June 23, from heart disease.

Herman Wilkomir Katz, Elizabeth, N. J.; Albany (N. Y.) Medical College, 1897; aged 47; died at his home, June 19.

Annie Davis, Hamilton, Ont.; Trinity University, Toronto, 1902; aged 45; died at her home, March 5, from anemia.

Thomas A. Smith, Marshall, Mo.; Washington University, St. Louis, 1880; aged 60; died at his home, May 20.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION.

PROTEOGENS OF THE WM. S. MERRELL COMPANY

Report of the Council on Pharmacy and Chemistry

The Council has adopted and authorized publication of the statement which appears below, declaring Proteogen No. 1 (Plantex) for Cancer, Proteogen No. 2 for Rheumatism, Proteogen No. 3 for Tuberculosis, Proteogen No. 4 for Hay Fever and Bronchial Asthma, Proteogen No. 5 for Dermatoses, Proteogen No. 6 for Chlorosis, Proteogen No. 7 for Secondary Anemia, Proteogen No. 8 for Pernicious Anemia, Proteogen No. 9 for Goitre, Proteogen No. 10 for Syphilis, Proteogen No. 11 for Gonorrhea, and Proteogen No. 12 for Influenza and Pneumonia inadmissible to New and Non-official Remedies because their composition is secret; because the therapeutic claims made for them are unwarranted; and because the secrecy and complexity of their composition makes the use of these preparations irrational.

The Council took up the consideration of the Merrell Proteogens because of inquiries received, and on January 27 invited the Merrell Company to aid in the proposed investigation by submitting information in regard to the composition of the preparations, submitting the current advertising, and presenting evidence for the claims that were made for the preparations. While the Merrell Company agreed to submit the requested information, this had not been received at the time the report of the referee to whom the products had been assigned (Referee 1), was adopted. This report was sent to the company on April 4. In reply the Merrell Company protested against the conclusions of the report and submitted considerable material in an attempt to support the claims made for the products. This material was examined by the first referee and then transmitted to a second referee (Referee 2) for consideration. The second referee concluded that the matter submitted offered no evidence that would justify the Council in modifying the report first adopted, and hence recommended that its publication be authorized.

In accordance with this recommendation (report of Referee 2), the Council authorized the publication of the reports of both the first and second referees.

W. A. PUCKNER, Secretary.

Report of First Referee on Proteogens

"Proteogens," according to the William S. Merrell Co., are "Polyvalent Proteins of Non-Toxic Plant Origin." The subject of Proteogens can best be approached by recalling the history of "Autolysin," an alleged remedy for cancer, originated by A. S. Horowitz, Ph.D. This was exploited some years ago, and was finally shown to be worthless. Proteogens are said to be prepared "under the personal supervision of the originator, Dr. A. S. Horowitz." The composition of the different Proteogens is essentially secret. The assertion was made at one time, but is not found in the present advertising matter, that Plantex—now called "Proteogen No. 1"—is similar to Autolysin. Now the Proteogens are said to be "prepared by a special process employing various combinations of plants." Further:

"The biologic principles present are chlorophyll, chromoid, lipoids and vitamins; these are ferments or enzymes. The vegetable acids, essential oils and minerals present in all plants in colloid form act biochemically. Among the metalloids are hydrogen, carbon, manganese, oxygen, sulphur, phosphorus and chlorine; the heavy metals are iron, potassium, sodium, magnesium and copper. These biochemic principles are always present in plants as colloids."

It is claimed by the Merrell Company that:

"Proteogens stimulate the cytogenic mechanism to higher activity; therefore, indirectly drive the invading microorganism and eliminate their special toxins. Proteogens swing the disturbed metabolism back to normal and, by natural processes, build up effective defenses against recurrent bacterial attacks."

Proteogen No. 1 was first introduced as "Plantex," and at that time the Merrell Company referred to a preparation that was the result of "a series of studies" carried out by a "noted biologist" with a view of "evolving a Cancer remedy" that was "to be autolytic in character," and announced:

"The House of Merrell always interested in the progress of plant therapy, began pharmacological experimentations to reproduce this same substance. The qualitative and quantitative analysis of the substance as used in New York having been published simplified matters. A somewhat similar remedy has now been prepared. It consists of the following substances—*Menyanthes trifoliata* (Buckbean), *Melilotus officinalis* (Yellow sweet clover), *Mentha crispa* (Curled mint), *Brassica alba* (White mustard), *Anemone hepatica* (Liver leaf), *Viola tricolor* (Pansy), *Anthemis* (Roman chamomile), *Fructus colocyntidis* (Colocynth), *Lignum quassia* (Quassia) *Urtica dioica* (Nettle), *Radix rhei* (Rhubarb root), *Hedge hyssop*. These substances are in approximately equal proportions with the exception of the mustard which forms 20 per cent. of the mixture, and the colocynth fruit which is 5 per cent."

With respect also to the other Proteogens listed above, study of medical literature revealed no evidence establishing their therapeutic value; in fact, no evidence was found other than that appearing in the advertising matter of the manufacturer. The range of diseases in which Proteogens are recommended is so wide as to make obvious the lack of scientific judgment which characterizes their exploitation. A circular letter, received January, 1919, reminded the physician that about a year ago his attention had been directed to Proteogen No. 1 for cancer, that later developments enabled the firm to recommend for his consideration "a series of Proteogens (Nos. 2 to 9)," and that now "In response to an insistent demand, Dr. A. S. Horowitz has prepared two new Proteogens—No. 10 for Syphilis and No. 11 for Gonorrhea." A postscript to this circular letter announced another preparation, "Proteogen No. 12 for Influenza and Pneumonia," a "development out of the present influenza epidemic," and admitted that "It has not had the clinical experimentation that precedes our introduction of a new product."

The introduction of No. 12 was effected by means of a special bulletin which consists exclusively of clinical reports from seven physicians, all from Chicago save one, and all purporting to show most favorable results from No. 12. They describe cases which any physician with experience with influenza can duplicate without any special treatment.

It is difficult to give serious consideration to a set of alleged remedies when the only evidence is that furnished by the proponents of the alleged remedies. This is particularly true when the alleged remedy does not make a sufficient appeal to one's sense of the rational in therapeutics to lead one to feel justified in asking a trial at the hands of careful clinical observers. Considering the grave nature of the diseases for which Proteogens are recommended, particularly cancer, tuberculosis, and pernicious anemia, the want of a rational basis for the method of treatment and the general tenor of the advertising matter, it appears safe to conclude that these agents do not represent any definite advance in therapeutics.

As the use of preparations, secret in composition, and of no established value, is contrary to rational therapy, it is recommended that the Proteogen preparations be declared in conflict with Rules 1, 6 and 10.

Report of Second Referee Reviewing Manufacturers' Reply

The report declaring the Proteogens of the William S. Merrell Company inadmissible to New and Nonofficial Remedies was adopted by the Council, but before publication it was sent to the Merrell Company for such comments as it might desire to make. In due time the reply of the firm was received. It consisted of two volumes bound in limp morocco, each stamped in gold: "Report Proteogen Therapy Requested by the American Medical Association, 1919; The Wm. S. Merrell Company." The first volume contained 79 pages of typewritten material; the second volume contained 76 pages of typewritten material and a number of advertising booklets put out by the Wm. S. Merrell Company, exploiting the Proteogens.

Among the typewritten material was a 14-page report on "Proteogen Therapy" by its originator, A. S. Horowitz. Following this there are several pages devoted to what is termed

"a short qualitative description of the ingredients of major importance in Proteogens." Then follows a page describing the advertising of Proteogens, and the remainder of the two books is devoted to testimonials, lauding the benefit of Proteogens in diseases such as cancer, tuberculosis, rheumatism, asthma, influenza, enlarged prostate, rheumatic endocarditis, syphilis, eczema, psoriasis, diabetes, secondary anemia, gonococcal infections etc. Finally, there are attached samples of advertising pamphlets.

The dissertation by A. S. Horowitz contains little actual information concerning these substances, but is concerned principally with discussion of foreign proteins, "antiferments," "non-specific proteins," "anti-virolins" and speculations on their hypothetical actions and interactions on each other and on the organs of the body and on bacteria. The report contains many questionable statements.

One finds in this report but few definite statements of facts which are known to be accurate or which could be accepted without question. The qualitative description of the proteins and their components is as vague as the previous discussion. The differentiation between the various Proteogens is extremely indefinite; that for Tuberculosis, No. 3 is described as "polyvalent, non-specific protein which rapidly attacks the acid-fast, encapsulated tubercle bacilli"; Proteogen No. 10 for syphilis is said to be a combination of "non-specific plant proteins and different chemicals which has the power to paralyze and destroy living spirochete." It is stated that Proteogens are scientific preparations based on standard ingredients and that the standardization is more accurate than in serums, vaccines or toxins, etc. The report gives no proof of such statements.

The testimonials that are submitted are typical of "reports" that manufacturers are able to obtain from some physicians, to prove the efficacy of almost any preparation in any disease. Each consists, practically, of the opinion of the individual who has employed the Proteogens or the opinion of the patient who has been treated. Few data are given in these reports from which an impartial conclusion might be drawn. A few of the testimonials presented by the William S. Merrell Company follow. The valuelessness of such material as scientific evidence is obvious:

RHEUMATISM—Proteogen No. 2.—The Doctor has one case being treated with No. 2. She has improved so rapidly she cannot express her pleasure, and will continue for some time on the treatments. She

is a patient who was confined during the time she suffered from a rheumatic illness, and it seemed to affect her mental condition. This condition is clearing up also, very much to the pleasure of both patient and doctor.—November 27, 1918.

INFLUENZA—Proteogen No. 12.—First day, temperature 102, gave 1 c.c. Proteogen No. 12; second day, temperature 100, gave 1 c.c. Proteogen No. 12; third day, temperature 99.8, gave 1 c.c. Proteogen No. 12, and then discharged the case as recovered.—October 31, 1918.

ASTHMA—Proteogen No. 4.—Splendid results obtained from a sample of Proteogen No. 4. Three ampoules affected [effect?] complete recovery.—October 9, 1918.

CANCER—Proteogen No. 1.—Mrs. B. pronounced recovered from Cancer by Dr. O. W. A. of Catlin, after having injections of Proteogen No. 1 for some time.—October 4, 1918.

ECZEMA—Proteogen No. 5.—Tried No. 5 on a patient with eczema, and with happy results. Have not done

anything for him for about five months—and he is now at his business. Proteogen No. 5 also relieved him of CONSTIPATION AND WHAT HE CLAIMED A TRAUMATIC STRICTURE OF THE LOWER PORTION OF SIGMOID FLEXURE. He is sure pleased and recommending them to his friends. (Proteogens).—February 17, 1919.

SYPHILIS—Proteogen No. 10.—I am getting such excellent results with the No. 10 Proteogen for Syphilis that I am bold in need of more, as I am treating so many cases. Please send me four dozen C. O. D.—October 9, 1918.

ENLARGED PROSTATE—Proteogen No. 1.—Have used Plantez in enlarged prostate in four cases, with good results in each case. One of them his father, an elderly man. April 25, 1918.

LOBAR PNEUMONIA—Proteogen No. 12.—The only case I have used Proteogen No. 12, was a man who had Lobar Pneumonia of left lung following Influenza. After crisis came, patient continued to have slight rise in temperature, cough, and after using 10 doses of your Proteogen No. 12, temperature was normal, cough very much better, patient began to take on flesh and is still improving.—December 26, 1918.

TUBERCULOSIS—Proteogen No. 3.—The Doctor writes: The Proteogen No. 3 sent me worked wonders in my patient. The case came under my care when he was too far gone for anything to benefit him a great deal, but the Proteogen did for him more than anyone could have expected, yet he died leaving me with a few ampoules to try on the next patient.—September 20, 1918.

GONORRHEAL CYSTITIS—Proteogen No. 11.—My patient has taken two boxes of your Proteogen No. 11 given for gonorrheal cystitis of probably two years' standing and at this writing I consider her almost, if not entirely, cured which I think speaks very highly of your remedy. I expect to use more of your preparations in the future.—April 12, 1919. [This testimonial, either by clerical error, or because the results were considered remarkable, was repeated elsewhere in the material submitted by the Merrell Company.]

ACUTE GONORRHEA—Proteogen No. 11.—Mr. A. F. R., age 65, weight 140 pounds. First attack. Had had no previous treatment. Came to me January 2, 1919. Had discharge, all acute symptoms, burning, etc. Gave seventeen injections of Proteogen No. 11, also mild antiseptic urethral wash. Discharged on February 15, 1919, clinically cured.—April 11, 1919.

June 28, 1919]

MEDICAL RECORD.

25

War Department Surgeon General's Office Washington, D. C.

I beg to state that the bacteriological and comparative tests made by me of Tyree's Antiseptic Powder were made from a sealed package of the product purchased in the open market.

The results of these experiments show that the prominence given this compound is well founded, for the preparation responds to all the requirements of a first class antiseptic and germicide, with practically no toxicity, which is certainly an advantage over the standard antiseptics, such as mercuric bichloride, carbolic acid and formaldehyde.

After a thorough investigation of Tyree's Antiseptic Powder, I conclude that its efficiency must be due to the exceptional purity of its ingredients, together with its well balanced chemical adjustment and the method of manufacture. My experience with this compound warrants me in believing that it is a most valuable and useful one.

My procedure in making the bacteriological tests of this powder, and of the three selected standard germicides, was as follows: Three different strength solutions of the powder, 1%, 2%, 5% were made up in sterile distilled water; at the same time solutions of mercuric bichloride 1:1000, carbolic acid 5% and formaldehyde 5% were prepared in same manner. To 5 c.c. of each of these different solutions in tubes was added two drops of a 24 hour old culture of a pus producing organism, staphylococcus proteus aureus, and to another set of tubes the same quantity of a spore producing organism, the bacillus anthracis, at periods varying from one minute to thirty minutes, incubations from these contaminated solutions were made into sterile bouillon tubes; these inoculated bouillon tubes were then placed in an incubator for 48 hours, at the end of which time the results were noted in the following tables.

These experiments were duplicated three times, with practically no variation.

From the following tables, it will be seen that even a 2% solution is equal in germicidal potency to mercuric bichloride, 1:1000, and greatly superior to carbolic acid 5%, and formaldehyde 5%. Repeated tests demonstrate conclusively that a 2% solution of Tyree's Antiseptic Powder is as germicidal in action as one of 5%.

W. M. GRAY, M. D.
Mercersburg Army Medical Museum,
Pathologist to Providence Hospital.

A detailed table of Professor Gray's analysis of Tyree's Antiseptic Powder will be mailed to the Surgeon General's Office upon request and a box of the powder enclosed herewith.

J. S. TYREE, Chemist, Inc., Washington, D. C.

Above is a greatly reduced photographic reproduction of a full page advertisement of Tyree's Antiseptic Powder. It has been appearing for some weeks in the New York Medical Record. Every person who sees this advertisement and is not familiar with the facts, must naturally suppose that the report of Dr. W. M. Gray, made on the stationery of the Surgeon General's Office, War Department, is a recent report, dealing with Tyree's Antiseptic Powder. As a matter of fact, the report was issued January 3, 1890, nearly thirty years ago and Dr. Gray, who made it, has been dead several years. Furthermore, the product that Dr. Gray analyzed was a different substance from the present Tyree's Antiseptic Powder. All these facts were brought out in THE JOURNAL A. M. A., May 17, 1919, yet the Medical Record persists in publishing this advertisement without explanations or apology. "That Tells the Whole Story."

EPITHELIOMA OF BUTTOCK:—*Proteogen* No. 1.—I used Proteogen No. 1 on an epithelioma of buttock some six months ago with favorable results and no return of symptoms as yet.—April 13, 1919.

It is obvious that the Proteogen preparations are in conflict with Rules 1, 6 and 10, and should not be admitted to "New and Nonofficial Remedies." It is recommended that the previous action of the Council be allowed to stand and that publication of both reports be authorized.

Correspondence

"THE ADMINISTRATION OF ARSPHENAMIN"

To the Editor:—Several criticisms of my letter (*THE JOURNAL*, May 10, p. 1389) on the administration of arspenamin have appeared and seem to demand the following comments:

Dr. Goldenberg (*THE JOURNAL*, May 31, p. 1634) uses only 20 c.c. of distilled water for 0.1 gm. of drug, two thirds of the amount for dilution that was suggested in my letter, and employs about half of the time I mentioned. Dr. Pusey (*THE JOURNAL*, June 14, p. 1786) approves from 20 to 25 c.c. per decigram, and Dr. Nelken (*THE JOURNAL*, June 7, p. 1695) uses a solution as concentrated as 0.6 gm. of the drug in 20 c.c. of water, and gives the dose in from 20 to 30 seconds.

No one knows how far concentration of drug and rapidity of administration may be carried without undue risk to the patient, and it is possible that the limits Dr. Goldenberg and Dr. Pusey set may be sufficient; though what is to be gained by using the 25 c.c. per 0.1 gm. mentioned by Dr. Pusey, or even the 20 c.c. mentioned by Dr. Goldenberg instead of the 30 c.c. mentioned by myself is not clear, as the difference is relatively small. The drug as used by Dr. Nelken is six times as concentrated as that employed by Dr. Goldenberg, and nine times as concentrated as that noted in my letter, and he gives it about twelve times as rapidly as does Dr. Goldenberg, and twenty-four times as rapidly as indicated in my letter. I suspect that if Dr. Nelken found himself facing responsibility for unfavorable results, following the use of arspenamin given in the way he advocates, he would get little more comfort from the evidence that Dr. Goldenberg or Dr. Pusey has contributed than from my own.

Perhaps Dr. Goldenberg or Dr. Pusey could suggest what they consider the safe minimum of dilution, which presumably lies between the amounts of fluid they use and that advocated by Dr. Nelken, and perhaps they could supplement this with the safe minimum of time of administration which might be required for the injection, which also presumably lies somewhere between the time used by themselves and that advocated by Dr. Nelken.

It is possible that the administration of arspenamin in somewhat more concentrated solution, and more rapidly injected than that recommended may be satisfactory; but the collected experience available at the Hygienic Laboratory shows that a very large proportion of the instances of severe or fatal reactions have been associated with high concentrations of this potent drug and rapid administrations, and that therefore it seems unwise to approve of a technic which varies materially from that indicated by me. Moreover, it is illogical and unscientific to charge unfavorable reactions to a preparation when in its administration the explicit directions of the manufacturer have been grossly deviated from. Not only can the preparation not be blamed under such circumstances, but indeed the physician himself might fairly be held responsible for any untoward results when the directions on the package have been materially deviated from.

Dr. Pusey appears to be of the opinion that the toxic reactions following the use of arspenamin are due to specimens of the drug that are "grossly contaminated." The fact, of course, is that even the purest arspenamin is a very toxic substance, and samples of what are, judged by all evidence at hand, of high quality may, in rare instances, give serious or fatal reactions. The earlier standards for the drug made in this country were made to accord as nearly as possible with those of the German product, which had been imported previously; but even this drug had a large

margin of safety, and, given well diluted and slowly, was a safe product.

Dr. Pusey calls attention to the fact that animal experiments show that arspenamin is less toxic when well diluted. While the Hygienic Laboratory has considered evidence from many sources, the purely experimental work on arspenamin had no part in formulating the suggestions made; the latter were based exclusively on clinical reports.

The records collected by the Hygienic Laboratory cover the experience of a large number of physicians who administer arspenamin. Our data were secured in response to a circular letter, published in the medical journals, requesting that reports be sent to us on all unfavorable results from the use of arspenamin, and from reports made on results in venereal disease clinics under state and federal direction (the latter reports being made in accordance with the instructions of the Surgeon-General of the U. S. Public Health Service). These data embraced many thousands of administrations of the drug.

This experience of the Hygienic Laboratory may be, as Dr. Pusey intimates, inadequate; but the indications it afforded were so clear that it was felt proper to make them the basis of the suggestions published in *THE JOURNAL*. Practically all of the fatalities and the severe reactions that have been reported to us were in cases in which the drug had been given in a concentrated form and given rapidly, or was mis-handled in some other manner; though, almost invariably, the attempt was made to place responsibility on the arspenamin. The most striking examples are briefly recorded here:

(a) A product which enjoys a particularly high reputation was held responsible by the physician for one fatal result and several severe reactions, though the same batch of the drug had been used by many others without unfavorable results, and in spite of the fact that in the cases in which he secured unfavorable results the drug was given in very concentrated form. The time of injection was too short, and there was doubt as to whether the proper amount of sodium hydroxid solution had been used.

(b) Another product was likewise misused by a physician, under almost the same circumstances as are related in the preceding paragraph. Here also there was one fatality and several severe reactions. The physician in this case was most emphatic in placing the responsibility on the particular brand of arspenamin, and insisted on the satisfactory nature of the technic of administration. He has since reported severe reactions from two other brands of arspenamin, both used in too concentrated form and given too rapidly.

(c) In a third case, several patients were injected and all gave "unusual and severe reactions," although the preparation was one which was highly satisfactory according to the animal test and which gave, so far as we know, no other unfavorable reactions. In reviewing the technic, the physicians responsible absolve the distilled water used, although it was old and contaminated with living micro-organisms, which they believed were killed by heating. They absolve the mode of administration, although the concentration given was a dose of approximately 0.45 gm. in 18 to 20 c.c. of water, and hold the drug itself responsible, stating: "By excluding all other factors, it would seem that this drug was responsible for the reactions."

(d) In another report bearing on a lot of the drug which proved satisfactory in the laboratory tests and which is not reported to have given any other unfavorable results, the physician himself noted that he got reactions only when the drug had been dissolved in warm water, and that reactions were absent when water at room temperature was used; he candidly remarks that the manufacturer's instructions carried a caution against dissolving the drug in hot water.

These are examples of the clinical reports, on the basis of which I felt justified in publishing the letter which has given rise to the controversy. There is no desire on my part, as Dr. Pusey puts it, to "saddle all arspenamin accidents on the technic," as I am sure these may occasionally occur when the technic is satisfactory; but I do object to saddling accidents on the drug when it has been used in a grossly improper fashion, and directly in conflict with the instructions of the manufacturer.

Arsphenamin is made in batches which go into anywhere from several hundred to several thousand ampules. Practically any batch of a product is likely to go into the hands of a number of physicians, and when only one of these registers complaint as to the quality of the drug, and the others use it with satisfaction, there seems to be no other conclusion than that the mode of administration in the exceptional case was at fault.

The study of the laboratory and clinical data we have at the Hygienic Laboratory indicates that the arsphenamin now produced by the various manufacturers varies but little, and all is of as high quality as the imported German product. Reports of serious or fatal reactions have been received covering the product of every licensed manufacturer, though the number of reactions in relation to the output of each plant is unknown.

How any physician can justify himself in administering a potent and toxic drug in high concentration, when every package carries a circular with explicit instructions to give it well diluted, is difficult to understand. Certainly, when the manufacturer's own instructions as to preparation for use are grossly violated, the producer has good grounds for claiming that unless the technic of administration was in accord with the instructions the drug should not be held to be at fault, without clear proof that it was to blame.

Physicians should recognize that by using a high concentration of the drug and giving it rapidly they afford the producer of even a poor batch a very satisfactory defense, as the methods many physicians employ introduce the very factors that make for the maximum of unfavorable reaction of even a good preparation, and make it impossible to prove that any preparation is poor. On the other hand, if the drug is used in accordance with the producer's instructions and unfavorable results follow, the case against the drug is strengthened.

G. W. McCoy, M.D., Washington, D. C.
Director, Hygienic Laboratory, U. S. P. H. S.

To the Editor:—In recent issues of THE JOURNAL there has been some discussion as to the propriety of giving neo-arsphenamin in concentrated solutions. While serving as urologist to the American Army Schools at Langres, I had considerable experience with this drug, and my observations may be of interest to your readers. It was the custom in the American Expeditionary Forces to give the French novarsobenzol brand of neo-arsphenamin in 2 c.c. of sterile distilled water. This technic was approved and adopted by the men in charge of the Urological Section of Medical and Surgical Consultants, and was described in the Manual of Military Urology, published for use by all urologists in the A. E. F.

The technic is simple. The neck of the ampule is filled and the tip broken off. An ampule containing 2 c.c. of sterile distilled water is then broken at both ends and the water allowed to flow into the ampule containing the neo-arsphenamin. Slight agitation effects solution very promptly, and the clear fluid is then drawn up in a hypodermic syringe of Luer type. By this technic the neo-arsphenamin is subjected to the minimum amount of transference from one receptacle to another, and the danger of contamination is reduced to a minimum.

During nine and a half months I employed this technic constantly, and must have given in the neighborhood of 600 to 700 injections personally. At the same time it was being administered in the area at various camps and dispensaries under my supervision, so that I think it safe to estimate that at least 2,000 injections were given during the period of my residence at Langres. I did not hear of a single case of any severe reaction. One patient used to vomit in the office after receiving his injection, but this was the utmost that ever happened. Two patients developed mild dermatitis.

It is a question whether a similar series of cases in support of any other technic could be adduced; the results, as far as severe reactions are concerned, were as good as could be obtained by any technic.

But apart from the question of severe reactions, there is another aspect which I think ought to be considered; that

is, the cost of adequate treatment to the patient. Speaking recently with a physician who employs old arsphenamin, I learned that he sterilizes all apparatus in an autoclave in order to avoid possible contamination from boiling in water which may contain mineral salts. It is exceedingly difficult to get a chemically pure sodium hydroxide, and sodium chloride may also contain impurities that are capable of reducing the arsphenamin. If filtered, one more transfer of the liquid becomes necessary with its accompanying chance of contamination.

The most rigid technic possible cannot exclude every possibility of contamination, reduction and consequent poisoning of our patient, but it can and does make the procedure a very expensive one, and this expense must be borne ultimately by the patient, unless the people are to be pauperized. The simple technic which I have described not only necessitates less exposure of our chemical to contamination and reduction, but also eliminates the labored technic formerly employed, and renders it possible for the physician to administer treatment at about the cost of an ordinary office visit, plus the actual cost of the chemicals employed.

As we wish to bring relief to the greatest number of people possible, it seems to me that this is a point worthy of the most careful consideration.

Severe reactions after giving neo-arsphenamin are almost certainly due to some fault in technic, avoidable or unavoidable, whereby the arsenical preparation undergoes some sort of reduction before administration, and I think we have ample evidence that the giving of the drug in concentrated solution is not, in itself, objectionable, and that it may even reduce the danger of decomposition, favored necessarily by excessive handling, transferring from one vessel to another, passage through filter papers, etc.

H. McCURE YOUNG, M.D., St. Louis.

DIPHTHERIC WOUND INFECTIONS

To the Editor:—In THE JOURNAL, Sept. 8, 1917, p. 791, we described an outbreak of wound diphtheria. This communication stimulated interest in the subject, and led to the publication of the results of several investigations notably those of Janes and Thomas (*Canadian Medical Association Journal*, May, 1919) and that of Adami and his collaborators (*Bulletin of the Canadian Army Medical Corps*, June, 1918).

We investigated carefully a considerable number of cases of diphtheric wound infections in the spring of 1917, and carried out virulence tests and protection experiments on several of the strains of *B. diphtheriae* isolated at that time. No endeavor was made to determine the virulence of every strain isolated, nor was any attempt made to ascertain precisely the proportion of wound infections which were due to *B. diphtheriae* in all of the cases studied. We contented ourselves with pointing out that we had observed an epidemic outbreak of wound diphtheria, and that "it was extremely probable that patients with diphtheric wound infections were being returned to Canada from overseas"; we suggested that a routine bacteriologic examination of all suppurating wounds be made, in order that wound infections due to *B. diphtheriae* might be discovered and appropriately dealt with, and, finally, we recommended that diphtheria antitoxin be used in the general treatment of the condition, in addition to any local treatment that might be tried.

The expansion of the literature dealing with this subject has been such that a brief summary of the present situation is probably desirable. Adami and his co-workers in their paper reported that in an investigation of 300 cases of infection of open wounds, they found only two which were caused by *B. diphtheriae*, and were therefore led to the conclusion that "there is a large body of evidence showing that even isolated cases of diphtheria infection of wounds are distinctly uncommon among the wounded overseas and complete absence of any evidence in Great Britain that these isolated cases have acted as foci for the spread of the infection to other wounded men. No evidence of a widespread infection of open wound by diphtheria bacilli has been discovered in Canadian hospitals overseas, in Great Britain."

We were not in a position to comment on the foregoing, nor indeed were we able to furnish conclusive evidence in our first communication as to the source of some of the diphtheric wound infections seen by us. That we observed an epidemic of diphtheric wound infections in military hospitals in Toronto, during the spring of 1917, has been definitely established and is one of the very few reports of actual epidemic outbreaks of this condition that has appeared in the literature. No evidence was brought forward by Adams to controvert our observations in regard to this outbreak.

The conclusion expressed in the paragraph quoted above, however, was very definitely opposed to the view that diphtheric wound infections contracted in England were being seen in men returned to Canada. It should be mentioned that the wounds observed by us were very largely in men who were returned to Canada from special military orthopedic hospitals in the United Kingdom.

Complete confirmation of the opinion expressed by us has just been furnished by James and Thomas. These observers, working as pathologists to the Granville Canadian Special Hospital, Buxton, England, have found that "from those cases in which pure cultures were obtained, 6.4 per cent. of open wounds in this hospital show infection with *Racillus diphtheriae*." We may safely infer, therefore, that the conclusions here arrived at entirely substantiate the inferences drawn by us as a result of our original observations.

The routine swabbing of suppurating open wounds practically eliminates the danger of an epidemic of diphtheric wound infection. That secondary cases of nose and throat diphtheria may arise from cases of diphtheric wound infections has been reported by Hartsell and Morris (*THE JOURNAL*, May 10, 1919, p. 1351), who describe an outbreak of throat diphtheria which occurred in a military base hospital in France. Infection remained a mystery until cases of wound diphtheria were discovered; then, with the establishment of strict quarantine and the adoption of "most careful wound technic," the outbreak was brought under control.

We would again recommend that both in civil and military hospitals a careful bacteriologic examination be made of all suppurating open wounds. We have pointed out that clinically the diagnosis between diphtheroid or other aerobic, and true diphtheric, wound infections cannot be made. It is necessary, if the diagnosis of wound diphtheria is to be definitely established, that a careful bacteriologic examination be undertaken which will include virulence tests and protection experiments.

It may not be feasible to undertake virulence and protection experiments in every case, especially early in an epidemic outbreak; but the true character of the infecting micro-organism should be definitely determined in at least a few cases at first, and if the outbreak is not almost at once controlled, routine virulence and protection tests made. This was the procedure adopted by us in our work done in the spring of 1917 in military hospitals in Military District No. 2, Toronto.

J. G. FITZGERALD, M.B.,
D. E. ROBERTSON, M.B., TORONTO.

ANDREAS CAESALPINUS: AN ANSWER

To the Editor:—In *THE JOURNAL* of June 21 is a current comment headed, "Andreas Caesalpinus," in which the writer in view of the fact that the present year marks the four hundredth anniversary of the birth of Caesalpinus, detracts somewhat from the claim that Caesalpinus had any great part or merit in the discovery of the circulation of the blood. The conclusions seem to be that Harvey was the real discoverer of the circulation of the blood, and that to him all honors are due.

Andreas Caesalpinus, whom the writer characterizes as a "botanist and writer on medical topics," was recognized in his day as the most learned man of his age, and his contemporaries called him "papa philosophorum" (father of philosophers). Aside from his contribution to the discovery of the circulation of the blood, he published a book, "*De Plantis*," which gives the best classification of plants up to

his time, and won for him undying fame as the forerunner of Linnaeus. In his book "*Quaestiones Peripateticæ*," published in 1593, Caesalpinus assumes a constant and physiologic transit of the blood from the arteries to the veins, through the anastomosis, which he termed the "*Vasa in capillamenta resoluta*," to every part of the body. This perpetual forward movement of the blood from the venae cavae to the right heart, thence to the lungs, from the lungs to the left heart, and from the left heart to the arteries, was termed by him "circulatio." He was the first to recognize the arterial structure of the pulsating vessels. He also recognized that the blood in the arteries stands at far higher pressure than that in the veins, and that in its passage from the one to the other, the capillary anastomosis offers greater or less resistance according to the degree of its contraction or dilatation. Again, in his work "*De Plantis*" Caesalpinus affirmed that the blood "per venas duci ad cor, et per arterias in universum corpus distribui (the blood is carried through the veins to the heart and through the arteries it is distributed through the whole body)." In the same year (1593), Caesalpinus published his "*Quaestionum Medicarum Libri II*," giving the experimental evidence of his theories. These experiments, which would be too long to enumerate and describe in an article of this kind, give the proof that his conclusion was based on rigid scientific studies.

I am not going into the controversy as to whom belongs the credit of the discovery of the pulmonary circulation—whether to Servetus or to Realduus Columbus. I wish, however, to call attention to the fact that Realduus Columbus was professor of anatomy at the University of Padua from 1542 to 1546, that he was the teacher of Caesalpinus, and that Servetus was also a student at the University of Padua. The Padua school was the real hotbed, at that time, for the overthrow of the Galenian doctrines, and the establishment of the new theories that led to the discovery of the circulation of the blood. Harvey arrived in Italy in the year 1598 and departed in 1603. In the meantime, he studied medicine at Padua, where he obtained his diploma in 1602. There can be no doubt that he was thoroughly acquainted with the work of Caesalpinus and Realduus Columbus. In fact, the works of Caesalpinus were so renowned that they had received the honor of four editions, one of which was edited in Padua. Caesalpinus' work "*De Plantis*" and the appendices to the "*Quaestiones Peripateticæ*" and to his "*De Plantis*," in which his theory of the circulation of the blood was repeated, were all published in 1603, the same year that Harvey left Padua. Harvey, while he was studying in Padua, no doubt attended the lectures of Eustachio Rudio, professor of the practice of medicine, in the university; therefore he must have been well acquainted with the bitter criticisms directed against Rudio, who wrote a book, "*De naturali ac morboza sanguinis constitutione*," in which he collected all the good and best of the doctrines of Caesalpinus and Columbus. Harvey has evidently made use of this work, reproducing even some of its errors, as has been demonstrated by Zecchi-nelli. Harvey in his work does not even mention the name of Columbus or Caesalpinus. He failed to mention and give proper credit to Cannani and Fabricius for the discovery of the valves in the veins. Also he failed to give proper credit to Paulus Sarpi for the demonstration of the function of the valves in favoring the centripetal flow of the blood in the veins, although in his demonstration of the circulation of the blood he made use of Sarpi's discovery.

His silence, when accused of plagiarism by his contemporaries, Micanzio, Vesling, Walaucus, Riolan, Bartholin and others, indicates that he prudently avoided a dispute in which he had much to lose and nothing to gain.

If a discovery is the act of finding out and bringing to public notice something unknown before, I cannot agree that to Harvey belongs the credit of the discovery of the circulation of the blood. Nevertheless, I recognize that Harvey's small book, which was published at Frankfurt in 1628, "*Exercitatio anatomica de motu cordis et sanguinis in animalibus*" is unmistakably the masterpiece of a man of genius. His many and original experiments on this subject and his coordinate arrangement of all knowledge pertaining to the circulation of the blood, are the real pillars to his glory.

Most of the data given in this article, have been taken (some verbatim), from Luciani's "Human Physiology," Vol. I, chapter on circulation of the blood, and from the annotations of Professor Antonelli to the anatomy of Hyrtl.

C. VOLINI, M.D., Chicago.

QUESTIONABLE LONGEVITY OF THE BULGARIANS

To the Editor:—Isn't it curious that generation after generation of medical men should continue apparently without question to accept Metchnikoff's statement about the longevity of the Bulgarians? I have heard his deductions questioned, but never his facts. Yet it should not require great acumen to infer that it would be extremely difficult to verify the ages of individuals among primitive peoples like those of eastern Europe.

My father was a missionary in Bulgaria for many years. He toured the country thoroughly and of course talked with any number of peasants. He has told me that one striking thing about peasant life in Bulgaria was the scarcity of old persons. People generally did not know their ages. But by inquiring about events they remembered, he was often able to make a good approximation. It was very rare that he found a person as old as 70. Men and women alike would look to be in the late seventies or eighties when they were in the fifties. The extremely hard life, and the absence of modern sanitation and knowledge of hygiene made them prematurely old and left them an easy prey to disease.

Metchnikoff, I presume, simply repeated another of the old wives' tales that make up so large a part of the supposed information on diet. His statement seems to have been taken as seriously as the Third George's inquiry why hot water froze sooner than cold.

H. J. HASKELL, Kansas City Star, Kansas City, Mo.

Queries and Minor Notes

ANSWER.—COMMUNICATIONS AND queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TREATMENT OF GONORRHEA

To the Editor:—In THE JOURNAL (April 26, 1919, p. 1255) there appears an abstract of an article by Pinedo and Baillet on the treatment of gonorrhea by pus vaccines. Will you please give me your opinion as to this treatment; and if favorable, the place where they may be obtained.

ENRIQUE ORASANOS, M.D., Torreón, Coah. Mexico.

ANSWER.—The vaccine mentioned above is not available for sale, as it was manufactured by the authors themselves for their own use. The treatment must be considered as being still in the experimental stage. It must also be noted that in this experiment there were no control cases treated with other vaccines. The authors, themselves, while claiming for it "incomparably better results" than with any vaccine previously used by them, recognize that only certain types of cases are benefited and that dangerous effects may result unless care is shown in selecting the cases and in the dosage. There is also the danger of inoculating the patient with "other bodies besides active gonococcal antigen, such as spores, etc." Until more evidence is available as to the merits of pus vaccine, the standard treatment of gonorrhea, such as described, for instance, in the Manual of Treatment of Venereal Diseases, should be depended on by the average physician.

PROTEOGEN

To the Editor:—Is there available information concerning a product exploited by William S. Merrill Company under the title "Proteogen"? They market "proteogens" for twelve distinct conditions. Their claims are extravagant. I wish to know whether the Council has investigated the product and what has been the verdict.

F. J. BOMBARDIER, M.D., Mapleton, Minn.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

NEW MEXICO: Santa Fe, July 14. Sec., Dr. R. E. McBride, 1130 Chaves.

Convention of the Catholic Hospital Association

The Catholic Hospital Association of United States and Canada held its fourth annual convention at St. Francis Xavier's Academy, Chicago, June 25-27. Rev. Charles B. Monlmer presiding. The main discussions were in regard to the organization of the staff with frequent regular meetings, laboratory in charge of a properly trained person to cooperate in all diagnoses, and case records from physical examination to end-results, in charge of a trained historian backed by the management. A most effective means of conducting the general discussion was a questionnaire pamphlet containing numerous questions sent in before the convention and answered on the floor by committees of specialists previously appointed by the chair. No uncertainty was allowed to prevail concerning the catholic adherence to the moral law and principles of the Catholic Church relating to hospital practice. Over 250 of the 652 Catholic hospitals in the United States and Canada and over 500, or one-fifth, of the doctors practicing in Catholic hospitals were reported as having joined the association. In the near future district or state branches of the association sufficiently small to comprehend local conditions will be organized and the work of these local units will be in charge of Rev. M. F. Griffin of Youngstown, Ohio. A monthly bulletin will be issued beginning in October, 1919. A committee will be appointed to plan for a Catholic training school for supervisors of nurses and superintendents of hospitals. Rev. Charles B. Monlmer of Milwaukee was reelected president, and Dr. Bernard F. McGrath, secretary-treasurer. The next convention will be held in St. Paul, June 23, 24 and 25, 1920.

Arizona January and April Examination

Dr. Allen H. Williams, secretary of the Board of Medical Examiners of Arizona, reports the oral and written examination held at Phoenix, Jan. 7-8, 1919. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 17 candidates examined, 16 passed, and 1 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
College of Physicians and Surgeons, Little Rock	1	(1908)	75.3
Chicago College of Medicine and Surgery	1	(1917)	84.6
Hahnemann Med. Coll. and Hosp., Chicago	1	(1913)	76.9
Jeffer Medical College	1	(1913)	80.7
College of Physicians and Surgeons, Keokuk	1	(1899)	80.7
Hospital College of Medicine, Louisville	1	(1906)	80.7
Kentucky School of Medicine	1	(1913)	81.7
Homeopathic Medical College of Missouri	1	(1899)	96
New York Homeopathic Medical Coll. and Hospital	1	(1899)	81.3
Federic Medical College	1	(1913)	81.3
Ohio State University College of Medicine	1	(1913)	75.3
Clatskanie Medical College	1	(1905)	75.3
Universities of Nashville and Tennessee	1	(1911)	85.6
Southwestern University Medical College	1	(1907)	85.6
National School of Homeo. Med., Mexico	1	(1911)	85.6

FAILED

John A. Creighton Medical College 1 | (1906) | 51.3 |

* The official records of the college named did not contain the name of this applicant.

† No grade given.

The examination held at Phoenix, April 1-2, 1919, covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Ten candidates were examined, all of whom passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Georgetown University	1	(1909)	85
Illinois Medical College	1	(1901)	76
College of Physicians and Surgeons, Chicago	1	(1901)	77.3
Tulane University	1	(1913)	80
University of Michigan	1	(1901)	85

Oklahoma January Report

Dr. J. J. Williams, secretary of the Oklahoma State Board of Medical Examiners, reports the written examination held at Oklahoma City, January 7-8, 1919. The examination covered 11 subjects and included 110 questions. An average of 70 per cent. was required to pass. Two candidates were examined, and passed. Thirteen candidates, including one osteopath, were licensed through reciprocity, and 8 candidates were granted registration certificates. The following colleges were represented:

Massachusetts March Examination

Dr. Walter P. Bowers, secretary of the Massachusetts Board of Registration in Medicine, reports the oral, written and practical examination held at Boston, March 11, 12 and 13, 1919. The examination covered 13 subjects and included 70 questions. An average of 75 per cent. was required to pass. Of the 116 candidates examined, 98, including 4 osteopaths, passed and 18, including 5 osteopaths failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.	
Howard University	(1888)	(1888)	77.7

* Graduated in medicine.

† The year of graduation is evidently not correct, as the college was not known by the name given until 1914. The registration, according to report, was not recognized by the Maryland Board of Medical Examiners.

Social Medicine, Medical Economics and Miscellany

Official Report on the Practice of Medicine by Unqualified Practitioners

As was mentioned in THE JOURNAL at the time, July, 1917, a commission was appointed by the public health authorities in the Netherlands, in response to considerable agitation and discussion on behalf of unqualified practitioners of medicine. The commission was given the task of settling the question as to the *doelmatigheid* of the unqualified practitioners, that is, to investigate their claims, their methods of treatment and the results attained. The commission was composed of twelve of the leading physicians and surgeons of the country, including Treub, Hijmans, van den Bergh, Pekelharing, Lamérís and Winkler. After nearly two years of research, their report has been published. It forms a quarto of sixty pages, and the main points have been summarized in the *Nederlandsch Tijdschrift*. Conditions were made extraordinarily favorable by the commission for the unqualified practitioners to present their patients for examination and control of the treatments and the results. They were universally invited, and when necessary the hospital, hotel and traveling expenses for both the unqualified and their patients were paid by the state. The members of the commission in nearly two years of work made a point of investigating only cases which they were able to examine beforehand themselves, not paying any attention to cases that dated from previous periods. It was found that the number of sick persons who were willing to submit to treatment by the unqualified was small, and only thirty unqualified practitioners were willing to submit patients to the commission's consideration, a total of ninety-six patients besides fifteen who were taking a course of treatment in a magnetic institute. The whole report is written from the objective standpoint with full details of the various cases.

The conclusions on the side of a favorable influence from the treatment by unqualified practitioners are: "The influence from suggestion exerted by certain unqualified 'healers' and probably also by the practitioners of Christian science may have a favorable action on sick persons. 2. Moreover, there are some among the unqualified persons who have become very skilful at massage. 3. It is also quite possible that the knowledge of the nature of a salve or mixture of herbs, the composition of which is kept secret, might prove of advantage in the treatment of certain definite affections."

The conclusions on the reverse side are: "The agitation and discussion during the last few years which resulted in the appointment of our commission make it incumbent on us to point out the great dangers to the public health which the results of the commission's investigations have established as inherent in allowing unqualified persons to practice medicine, dangers not only for the sick themselves but for the community at large. Our investigations have confirmed that in some cases, especially in the easily influenced or those with a leaning to mysticism, benefit may be realized from their complaints under treatment by magnetizers or other unqualified practitioners. When one is suffering from pains or does not feel well enough to attend to business, it is certainly an advantage for him if he does not feel the pain any more or if he is able to return blithely to work. But this is no proof that in reality he has been freed from his ailment. The unqualified, even the patients themselves, heed only the subjective complaints; the causes of the disturbances are hidden from them. Hence the numerous disappointments when after a period of transient improvement, the complaints return again and become accompanied by others on account of the progress of the malady, which with skilful examination and appropriate treatment in an earlier period might perhaps have been cured. Not one of the unqualified practitioners who submitted to examination displayed any knowledge of scientific medicine (*ziektkunde*). They use the names of diseases which they have heard from

others, or words such as 'glands,' without any meaning in the sense in which they are used. They undertake to treat the sick without any conception of the malady from which they are suffering, paying heed only to certain obvious and easily noted phenomena. In treating the sick with internal disease they are unable to determine whether the individual is suffering from an infectious disease, with danger of its spreading, and in this respect unqualified practitioners are a distinct menace to the public health. They have no means of knowing whether an internal affection may not require surgical help, and thus they are a menace to the health and even the life of the individual who has trusted himself to their care. When they take external diseases under treatment then they are dangerous on account of their lack of knowledge of the theory of infection."

School Health Work for the Small City

Recognizing the urgent demand for thorough and constructive health work in the public schools of its own state, and appreciating the difficulties of providing for this work in the manner of the larger cities where greater appropriations are available, the University of Oregon, through its extension division, in Leaflet Series 4, No. 8, Part 2, sets forth a plan for the organization of health work in the small city of from 5,000 to 15,000, prepared by W. R. Rutherford, superintendent of the schools of Eugene, Ore., after a study of the plans of such cities in forty-seven states. The nucleus of the plan is the health director, not necessarily a woman, but more likely to be, in the smaller city, who shall be in charge of all branches of health work in the schools. The health director should be a graduate, preferably, of one of the broad physical education courses now being conducted in some of the colleges, in view of the impossibility of employing on a full-time basis a competent physician, and should have available the paid or voluntary assistance of a good physician for help in diagnosis. Larger towns may afford a director, a nurse and a school physician. In this plan teachers should have a good knowledge of health matters as relates to the pupils and should participate in the work, coming in contact frequently with the director, whose enthusiasm should enlist their hearty cooperation. The chief features of the work have relation to the inspection of the pupils, and include the prompt recognition and handling of the contagious diseases; the establishment of health records and the elimination of physical defects; physical training; mental tests; health lessons, etc., including the hygiene and sanitation of the surroundings of the pupils. The pamphlet giving the details of the plan and a bibliography on school administration and health activities may be had from the extension department of the university at Eugene.

Fall from a Cliff 320 Feet High Without Fatal Injuries

An almost incredible case in which a soldier fell from a cliff 320 feet high without fatal injury is reported in the *Guy's Hospital Gazette* of Great Britain by Mr. Philip Turner. This accident occurred near a hospital camp situated on a level stretch of ground at the top of a chalk cliff between 300 and 350 feet high on the French coast. As is commonly the case with a chalk cliff, the face is practically perpendicular but decidedly irregular, there being a series of small bays and promontories. At 9 a. m., Dec. 9, 1916, Mr. Turner was informed that a man had fallen over the cliff and was being brought to the hospital. When first seen he was not unconscious, but was restless and delirious, and could not answer questions. His head and face were covered with blood, chalk and gravel, and his clothes, including a service great coat, were soaked with water and soiled with the same materials. He was soon identified as a private in a Canadian regiment who had been admitted into a neighboring hospital with a slight wound of the arm. This had healed, and he had been discharged to the convalescent depot in the same camp, where he had last been seen at 5:30 p. m. on the previous day. There were about ten scalp wounds, four of which extended down to the bone, and in one of these

in the right frontal region a fissured fracture of the skull of uncertain extent could be made out. There was no depressed fracture nor paralysis, the pupils were normal, and though there was bleeding from the nose, there was no hemorrhage from either external auditory meatus. There was a large wound of the right knee where a flap of superficial tissues was torn, opening up the popliteal space. There were a number of superficial cuts and contusions, but no fractures of any of the limb bones. It was thought that there was probably an extensive fracture of the base of the skull, and little hope was entertained of the man's recovery. After three days the delirium had diminished, but he was still unable to answer questions. The knee joint was found to have been opened and was washed out, the damaged portion of the capsule and the synovial membrane was excised, and the rent was sutured. The only sign of intracranial trouble was noticed, December 17, when there was slight left facial paralysis with inequality of pupils, the right being larger. A roentgenographic examination of the skull detected no definite injury. The man recovered with an ankylosed knee, but he had no recollection of leaving the camp or what he did on the night of December 8, or how he was injured. Some French laborers were at work on the beach at the time of the accident, and two of them noticed a falling object against the white surface of the cliff which struck and bounced from a ledge and fell on the beach. Mr. Turner thinks that the amnesia was due to some unrecognized mental or hysterical disturbance resulting from his having been under fire, which caused him to spend an inclement winter's night straying about and to wander on the cliff. He suggests that a possible explanation of this tremendous fall with so little injury was a strong wind that was blowing in from the sea, causing an up draft, especially at the cliff base of the bay. This might have got beneath the man's great coat, breaking the fall by producing a parachute effect.

The only comparable case on record occurred at Lulworth Cove on the Dorset coast. It is thus described by Sir Frederick Treves in "Highways and Byways in Dorset":

The cliffs that shut in the cove on the land side are steep and terrible. On the beach at the foot of the highest precipice is a beard with this inscription on it: "This marks the spot whereon E. H. L., aged 11 years, fell from the summit of the cliff, a descent of 280 feet, Sept. 7, 1892. She miraculously escaped without sustaining life-long injury." Any who look up from this spot to the fringe of grass which crowns this appalling wall will never credit that a child can have fallen from a height greater than that of St. Paul's Cathedral without having been mangled to death. I was on the beach when she was brought to the convalescent bouthouse. She came down with her back to the cliff. Her clothes were torn into shreds, and it would appear that the catching of her garments on the rough face of the precipice, together with the circumstances that certain slopes and ledges were encountered in her descent, help to explain the incredible fact that she escaped without permanent ill effect.

Education of the Organic Functions in Infancy

Sir Eric Pritchard (*Medical Press and Circular*, March 19, 1919) says it is too common a belief that the organic functions unfold themselves automatically on correct normal lines apart from the influence of the environment. In most cases they do, but they are largely under the control of human intelligence, and if directed unwisely give bad results, even permanently bad results. This applies especially to feeding habits. The neuromuscular mechanism by means of which food is swallowed, churned in the stomach and conveyed through the entire length of the intestines depends for its smooth working on accurate coordination of a vast number of involuntary muscles, some of which are specialized to constitute regular sphincters, while others carry out peristaltic functions. Overaction, perverted action or incoordinated action of these mechanisms is likely to result if the wrong sort of stimulus is provided in the first instance. It is important to set the mechanism in motion in the right way, at the beginning of life. An infant who in the first days of life swallows its food in a perfectly coordinated manner is not likely to develop any symptoms of dysphagia afterward. But if on account of food unsuited in either quality or quantity an infant acquires a faulty habit of swallowing, the

perverted function may remain permanently established no matter what steps may be taken to correct it. A form of this perverted function is called "rumination," which is a spasmodic closure of the cardiac sphincter, which leads to the retention of food in a dilated esophagus and the subsequent regurgitation of food which has never really entered the stomach. The motor mechanisms of the stomach are far more liable to be wrongly developed than those of the esophagus. Under normal conditions breast feeding induces normal evolution of gastric function, colostrum being especially perfectly adapted, by reason of its small quantity and stimulating qualities, to elicit the required motor response in the stomach, but causing no violent motor response of the pyloric sphincter or of the stomach. It gradually changes in a few days into ordinary milk and so calls the normal functions of the stomach into play. Cases of pyloric spasm constantly arise in young infants because of giving unduly large amounts of diluted cow's milk during the first few days of life. So-called wind in infants is generally caused by dysperistalsis or spasm of some section of the musculature of the intestine, generally of the transverse colon, and is usually due to faulty education or overstimulation by excess of food, or by food of indigestible character. The spasm becomes habitual and tends to recur every day at the same time. Constipation or looseness of the bowels is also largely a matter of education. Interference with the functions of the rectum and anus by the favorite dose of castor oil is likely to cause the establishment of faulty and incoordinated reactions, by clearing the bowel at one fell swoop of the beneficent meconium which is intended to educate the rectum in the functions of defecation.

New York's Health Record for 1918

The report on vital statistics for 1918 has been made public by Dr. William H. Guilfoyle, registrar of records of the department of health. Up to the time of the outbreak of the influenza epidemic, New York was on the way to establish a new low mortality record. Unfortunately, this was not realized, and owing to the many deaths from influenza the annual death rate was 17.30, almost four points above the annual death rate for several recent years. The influenza epidemic increased not only the adult death rate, but also that of children under 5 years of age, there being 21,019 deaths in this group, or 2,754 more than in 1917. The large increase in the death rate was almost entirely due to influenza, there being only 196 deaths from typhoid fever, as against 229 for 1917, and only eight deaths from malaria, as against 250 in other recent years. There was no death from smallpox. There was a slight increase in the number of deaths from measles and scarlet fever, but a decrease in the number of deaths from diphtheria. There were 665 deaths from whooping cough during 1918, as against 489 in 1917. The number of deaths from pulmonary tuberculosis was 8,779, as against 8,825 for 1917. The report states that 4,139 persons died from cancer, with a rate of 84 per hundred thousand of the population, as against 4,897, and a rate of 85 during 1917. This is considered encouraging, as the trend of mortality from this cause has been steadily upward for twenty years. The statistics show that influenza had no effect on organic heart and kidney diseases. The general infant mortality table showed that 12,637 infants under 1 year of age died, with a rate of 92 for each thousand births, as against a rate of 89 in each thousand births in 1917. From Sept. 14, 1918, to March 10, 1919, there were 15,000 deaths reported from influenza, 6,000 from bronchopneumonia, and 10,775 from lobar pneumonia, 32,785 deaths all told from these causes. The annual death rate from these causes for the quinquennium 1913-1917 averaged 10,996. The number of births reported was 138,046, as compared with 141,564 in 1917. The birth rate was 23.51 per thousand of the population, the lowest the city has experienced since records have been kept. The number of marriages reported was 56,733, with a rate of 9.66 per hundred thousand of the population, as against 59,212 during the year 1917.

Medicolegal

Proof of Other Dates of Holding Out as Practitioner

(Commonwealth v. Range (Mass.), 121 N. E. R. 449)

The Supreme Judicial Court of Massachusetts says that the defendant was charged with having unlawfully held himself out "as a practitioner of medicine" (in violation of Revised Laws, Chapter 76, Section 8), between March 3, 1915, and Aug. 3, 1915. At the trial the government did not put in evidence any such act between the dates named. But it did introduce evidence of one such act on Feb. 21, 1914, and of another on Feb. 12, 1915. The presiding judge instructed the jury that, if the defendant held himself out as a practitioner of medicine on any occasion preceding the date alleged in the complaint and within a period of six years next before that date, they could find the defendant guilty. To this ruling the defendant took an exception, and the exception must be sustained, and a new trial had. The offense created by said Section 8 may be committed by a single act or by a series of continuous acts; that is to say, it may consist of a single offense or of a continuing offense. In this case the government elected to charge the defendant with a series of acts committed between March 3, 1915, and Aug. 3, 1915, which constituted the continuing offense of illegally holding himself out as a practitioner of medicine. When a defendant is charged with a series of acts as a continuing offense, the offense charged in a single indivisible offense and a part of the description of the offense charged is the duration of time mentioned during which it is charged in the indictment the series of acts took place. It is for this reason that evidence of acts committed outside the time specified are not permissible in evidence. The district attorney argued that this had been changed by Section 10 of the act for the simplification of criminal pleading, but that section does not apply where time is an essential element of the crime.

Evidence in Action for Services Opposed by Claim of Malpractice

(MacCoy v. Gage (Calif.), 177 Pac. R. 296)

The District Court of Appeal of California, Second District, affirms a judgment in favor of the plaintiff, a licensed physician and surgeon, for \$1,000, the full amount sued for and alleged to be the reasonable value of professional services rendered to the defendant, who filed a cross-complaint, seeking to recover damages which he alleged he had sustained by reason of unskilful treatment which he had received at the hands of the plaintiff. The court says it appeared that the plaintiff had been called on to attend the defendant, who had suffered a fracture of the neck of the femur. At his first visit the plaintiff adjusted the broken part and applied a weight to the limb. A trained nurse was called to attend the case, and the plaintiff continued his ministrations during several months, and until the defendant was able to move about on crutches. It was shown that the patient later became able to walk, even without the aid of a cane, at least for short distances. The plaintiff made eighty-five visits to the defendant. During the time he attended him he was called on to prescribe for other conditions than the broken bone, namely, pneumonia and rheumatism. From all of the medical testimony, even that produced by the defendant, it appeared that so far as the fracture was concerned, the results obtained by the plaintiff were better than the average. Under the evidence as presented, it was very clear that the matter of the value to be placed on the services rendered to the defendant was one exclusively for the jury.

A medical witness having stated his opinion as to the value of the services rendered by the plaintiff, what these services had been being detailed in the question, objection was properly sustained to a question asked on cross-examination, whether the witness would alter his opinion as to the value of the services, when this question assumed other matters not shown in evidence. And when the same witness was asked, on cross-examination, as to whether it was not customary, in cases of the character involved, to take a recit-

genogram, the court cannot see how any prejudice resulted to the defendant by the sustaining of an objection to the question, even if it were to be conceded that the trial judge should have allowed the question to be answered. Concededly, the taking of a roentgenogram was valuable only for purposes of diagnosis, and it seemed very clear that the diagnosis made by the plaintiff without the aid of the roentgen ray was the correct one. More than this, the matter of the advisability and value of roentgenograms was fully gone into in the testimony introduced later in the case. The court thinks also that a refusal to permit counsel for the defendant to require the same witness to give in detail what he considered proper treatment to a patient under the circumstances shown was without error prejudicial to the defendant. The court did not debar the defendant from cross-examining on all matters contained in the hypothetical question on which the witness had answered in giving his opinion as to the value of the services, and it was within the court's discretion to refuse to allow the witness to enter on a discussion, possibly lengthy, as to a course of treatment not included within the facts as shown and on which he based his opinion as to the value of the services rendered.

Nor was there error in sustaining objections to questions asked the trained nurse who had attended the defendant under the direction of the plaintiff. The questions all went to the point as to what the witness had observed other physicians do in like cases, or what she considered good or customary treatment. The court does not think that the opinion of the trained nurse was competent evidence to show that the treatment administered by the plaintiff was improper.

Purchaser of Good Will Injured as Oculist

(*Ferris v. Pett* (R. I.), 105 Atl. R. 569)

The Supreme Court of Rhode Island says that, after the death of a Dr. Jewett, who had specialized in matters pertaining to the eye, ear, nose and throat, with practice as an oculist, the plaintiff, as administrator of his estate, contracted for the sale of his business, good will, surgical instruments, and furniture for \$1,000, to the defendant, another specialist in the same lines. After making payments aggregating \$500, the defendant refused to make further payments under the contract, on the ground that the plaintiff, who was an optician, had broken the contract on his part by interfering with the defendant's rights and impairing and injuring the good will, by solicitations addressed to the former patients of Dr. Jewett and designed to divert them from the defendant and secure to himself their future patronage. This action was then brought by the plaintiff, as administrator, to recover the balance which he claimed to be due under the contract. He recovered judgment for \$500 and interest, but the supreme court thinks that the solicitations of the plaintiff, as evidenced by his letters to former patients of Dr. Jewett, amounted to a violation of the contract on his part, and that he was not entitled to recover that portion of the contract price which appertained to the good will, and suggested that he show cause, if any he had, why this case should not be remitted to the lower court with direction to enter judgment for the defendant. It appeared that the plaintiff, as an optician, had copies of prescriptions that had emanated from Dr. Jewett, and had written letters to the effect that, in going over his files, he found the name of the person addressed and prescription for glasses as made by Dr. Jewett some little time before; that in most cases like that of the person addressed, a change of lenses was advisable after such a period, and so he was writing to inquire if the party would like to make appointment with him for a reexamination. The court says that there is no conflict of interest between the oculist and the optician, so long as the one prescribes the lenses, and the other prepares and adjusts them to suitable frames, in which they become practically effective. In this case the plaintiff went farther, as his letters of solicitation clearly indicated. In these letters he not only suggested that the party addressed should obtain new glasses from him, but that he or she should undergo, at his hands, a reexamination of the eyes, with a view to adapting future glasses to such changed conditions as might have resulted from the lapse of time. The court cannot see how the kind or degree

of skill required in determining what lenses were suited to the changed conditions would differ from that demanded in prescribing glasses in the first instance. The defendant testified that he received practically no advantage from the purchase of the good will of the business which had been carried on by Dr. Jewett. That fact would not in itself have any important bearing on his liability to pay the balance due under the contract. His mere failure to realize his expectations as to future business, in the absence of any fraud or interference on the part of the person from whom he made the purchase, would not establish a failure of consideration. But in this case there was something more to be considered than a failure of the defendant's expectations. The testimony disclosed that the plaintiff, after disposing of the good will of the business carried on by Dr. Jewett, interfered with the defendant's rights, and sought to divert the business from the defendant, for his own benefit, which clearly amounted to a violation of the contract on his part.

Scope of Review of Action of Board Revoking License

(*State Board of Medical Examiners v. Noble* (C. Co.), 177 Pac. R. 111)

The Supreme Court of Colorado reverses a judgment of the district court entered on a writ of certiorari to the state board of medical examiners, which judgment reversed the action of the board in revoking the license of Noble to practice medicine in the state. The supreme court says that the board, on a hearing, had on a complaint charging Noble with having committed an abortion found him guilty as charged, and revoked his license. In the trial court it was contended that a judgment of acquittal in the criminal court, on a charge of having committed an abortion, was a determination of his innocence which the state board was bound to accept, and it was so contended here. But that went to the merits of the cause, which was not involved in this proceeding. The medical board had jurisdiction of the subject and of the person, and clearly did not exceed jurisdiction, or abuse its discretion. On a review of its action by writ of certiorari, those were the only questions to be considered. Whether its decision on the merits was right or wrong was not within the issue. No complaint was made that Noble did not have a fair hearing before the board, and that body's action was within the authority granted it by law. The judgment of the district court was unauthorized.

Compensation for Both Injuries and Malpractice

(*Smith v. Battjes Fuel & Building Material Co., et al.* (Mich.), 169 N. W. R. 943)

The Supreme Court of Michigan affirms an order of the industrial accident board denying the petitions of the company, Smith's one-time employer, and of the state accident fund, insurer, for the right to cease further payments to Smith as compensation under the workmen's compensation act, because he had received \$2,125 from the physician who had treated him, on account of alleged malpractice in connection with the injury for which he claimed compensation, and for the reason that he had refused to submit to an operation. The court says that Smith had received an accidental injury in which his right arm was broken in at least two places, accompanied by a partial dislocation of the elbow joint. Thereafter a written agreement was entered into between him and the commissioner of insurance (the risk being carried by the state accident fund), by the terms of which he was to receive \$6.49 per week during disability. Some months later, becoming convinced that the then condition of his arm, which was entirely useless, was due to malpractice on the part of the attending physician, he sued him therefor, and was paid \$2,125 in settlement. The industrial accident board found that Smith's condition, which was one of total disability, was due to the original accident, and not to any malpractice; that his refusal to submit to proposed surgical operations on his arm, under the testimony in the case, was not unreasonable; that his receipt of the money from the physician did not constitute an election, within the meaning of the workmen's compensation act; and that the allegations in his declaration filed against the physician were not binding and conclusive on him, but might be

considered as evidence only. The court does not think that the fact that Smith started suit against the physician by declaration in which he averred that his condition of total disability was the result of malpractice, and not of the original accident, precluded him from asserting here that such condition was due to the original injury. The court is of the opinion that the board was correct in holding that the averments of the declaration were not conclusive as admissions against him, but might be considered by the board as evidence in connection with all the other evidence in the case. Nor does the court think that the state accident fund should have credit for the \$2,125 received by Smith from the physician, in reduction of the amount due from it to him under the terms of the statute. The Michigan law makes no provision for the application of sums received by a claimant from a third party, not connected with the original accident, in reduction of the master's liability under the act. If such application should be made, it is a matter for legislative action, rather than judicial interpretation.

Society Proceedings

AMERICAN PEDIATRIC SOCIETY

Thirty-First Annual Meeting, held in Atlantic City, N. J., June 16-18, 1919

The President, DR. EDWIN E. GRAHAM, Philadelphia,
in the Chair

Foreign Bodies in the Air and Food Passages

DR. EDWIN E. GRAHAM, Philadelphia: From a study of a comparatively large number of cases of foreign body in the air passages and a much smaller number of cases of foreign body in the food passages, it seems reasonable to conclude that foreign bodies in the air and food passages in children are much more common than has been supposed. Statistics tend to show that about 60 per cent. of the cases of foreign body in the air passages occurred in children. The period of latency of symptoms which follows the violent dyspnea and choking attack, and later the gradual onset and chronic character of the symptoms, may lead to failure to suspect the presence of a foreign body. Some foreign bodies do not cast a shadow on the roentgenogram. The physical signs and symptoms vary according to the composition, form, shape and size of the foreign body. A foreign body should be expected if the following conditions are present: an unexplained leukocytosis; localized symptoms in one lung that do not clear up under treatment; absence of tubercle bacilli in the sputum, and a gradual failure in weight and strength. There are no contraindications to bronchoscopy except weakness in the patient, and if this is present the individual should be given time to rally. Bronchoscopy should be performed as soon as possible after the entrance of the foreign body. Children do not require the administration of an anesthetic for the performing of bronchoscopy. The asthmatoïd wheeze is a symptom of considerable importance.

Lactose, Fat and Protein Content of Woman's Milk

DR. FRITZ B. TALBOT, Buffalo: Investigations on the composition of woman's milk at different stages of lactation, accurately quantitated by newer chemical methods, show that the average amount of lactose in sixty samples of breast milk was 7.19 per cent., with the general tendency for the strength of the lactose to increase throughout the period of lactation. The percentage of fat in the milk of different women varied within wide limits, the lowest mixed milk being 1.5 per cent. and the highest 9.9 per cent. The average amount in the mixed samples was 3 per cent. The average amount of fat in thirty-five samples taken only from wet-nurses was 4.18. The percentage of fat depends more on how completely the breasts are drained and the amount of the late milk which gets into the sample than on the stage of lactation. There is a general tendency for the amount of protein to diminish as lactation progresses. The variation in the percentage of lactose from the beginning to the

end of nursing rarely exceeded 1 per cent. The variation in the percentage of fat was greater, but, as a rule, it was less than 4 per cent. The percentage of protein rarely varied more than a few tenths of 1 per cent. and was sometimes lower after nursing and sometimes higher. The milk from the right and left breast of the same woman taken at about the same time tends to have about the same composition, but occasionally a wide variation is found. Milk taken at three hour periods during the day showed that as the day went on the volume of milk had a tendency to diminish. The percentage of fat was found to be higher after midday as a rule. The variation in the amount of lactose and protein, however, was very slight.

DISCUSSION

DR. L. EMMETT HOLT, New York: The figures Dr. Talbot has given for lactose are about what we have found in our laboratory. Many disturbances of digestion attributed to fat are in reality due to sugar. A baby may be gaining in weight and yet have a diarrhea due to the volatile fatty acids caused by sugar. Clinically the way to handle these cases is to dilute the milk and change the frequency of feeding. In such cases, examination of the stools may reveal the presence of fat; this leads to the erroneous assumption that it is the fat in the diet that is responsible for the trouble, whereas the stools contain fat because the fermentation of the sugar causes diarrhea and interferes with the digestion and absorption of fat. We must get away from the idea that breast milk always contains 7 per cent. of sugar or less, and we must learn that many disturbances of digestion may be attributed to sugar.

DR. DE WITT H. SHERMAN, Buffalo: If the protein content of the milk bears no relation to the high carbohydrate content, would it not be possible to overcome the conditions caused by a high percentage of sugar by the addition of some powdered protein preparation, thus changing the ratio of the food elements?

DR. FRITZ B. TALBOT, Buffalo: Children in the later stages of lactation who were getting 8 per cent. lactose were without watery stools, and we have fed this amount of sugar in the form of lactose and glucose without causing disturbance; so we have concluded that this is a normal ratio for this period of lactation. As to Dr. Sherman's question, we feel that the way to deal with sugar fermentation is to reduce the amount of sugar and that will stop the diarrhea.

Pathogenesis of Certain Nutritional Disorders

DR. W. McKIM MARRIOTT, St. Louis: In the severe and acute toxic state observed in infants who have suffered from a severe watery diarrhea, the trouble has been attributed to "alimentary intoxication" because the administration of food resulted in an increase of all the symptoms. A more rational view is that the giving of food, especially easily fermentable carbohydrate, leads to increased water loss from the body by way of the bowel, and that the symptoms may be referred entirely to water loss. The blood plasma of infants suffering from this condition was invariably concentrated. The protein of the blood serum of normal infants averaged 6 per cent.; in those desiccated as the result of diarrhea, it might rise as high as 9 or 10 per cent. This desiccation explains the great loss in weight in these children. Decrease in blood volume diminishes volume flow and results in acidosis, and in addition there is a retention of acids in the body through failure of excretion by the kidneys, since renal activity is greatly decreased by concentration of the blood and poor volume flow. Dehydration of the blood results in a disturbance of the heat regulatory mechanism, and fever occurs. The term "anhydremia" or "anhydremic intoxication" is accurately descriptive of the condition, and is preferable to the undesirable term of Finkelstein, "alimentary intoxication." Anhydremia occurs from other causes than diarrhea, as diminished fluid intake, or vomiting, fever or high external temperatures. Whatever the cause, the treatment is the same. Fluid in large amounts must be administered. The usual methods are often ineffective, and the intraperitoneal injections have to be given. A small infant may receive as much as 2,400 c.c. of fluid in twenty-four hours. The intravenous injection of 10 per

cent. glucose solution at frequent intervals is often a valuable adjunct to the saline injections. Marasmus is analogous to anhydremia, but is the result of insufficient food, whereas anhydremia is the result of insufficient water. In this condition there is a diminution in the blood protein, and the volume flow is also decreased, but not to such an extent as in anhydremia. The obvious treatment of these atrophic infants is the administration of considerable amounts of food. The best results in feeding in this type of cases has been obtained with whole lactic acid milk to which a mixture of carbohydrates is added, the most suitable carbohydrates being dextrin and glucose; maltose also is serviceable. "Corn syrup" is such a mixture and has proved most effective in our hands. Acacia injections are an adjunct but not a substitute for food.

DISCUSSION

DR. OSCAR M. SCHLOSS, New York: Pediatric literature contains many references to the digestibility of fat, protein and carbohydrate, but very little is said about water. A proper proportion of water is most important, as Dr. Marriott has shown. These children said to be suffering from alimentary intoxication are always in a state of dehydration. I have in a number of instances seen a marked acidosis disappear with the administration of a sufficient amount of water, without the use of sodium bicarbonate. The explanation is that given by Dr. Marriott.

DR. I. A. AET, Chicago: Many attempts have been made to classify intestinal disorders, both by clinicians and by bacteriologists, and we all know how futile such attempts have been. Now the chemists and the pathologists are trying their hand and I hope they will be successful. The most valuable classification we have is based on food disturbance. It seems that by noting the effects of certain foods in health and disease, the most important basis for the classification of nutritional disturbances would be furnished. Dr. Marriott has not referred to this side of the question; and while he has made an important contribution to the chemistry and pathology of these conditions, the important question is how to prevent the occurrence of a pathologic condition.

DR. McKIM MARRIOTT, St. Louis: I made no attempt to discuss the etiology of diarrhea. I feel that the prophylaxis of these underlying conditions is the prophylaxis of diarrhea, which we consider as a local condition in the intestinal tract, and merely the end result produced by any cause at all.

Study of Relationship of Convulsions in Infancy and Childhood to Epilepsy

DR. JOHN LOVETT MORSE, Boston: One hundred and seven persons whose primary complaint was convulsions were studied. No cases were included in which there were any evidences of acute or chronic cerebral disease. The objects of the study were to determine what proportion of the children, otherwise perfectly normal, having convulsions had epilepsy or developed it later, and to find out if there was anything in the history or in the manner of the development of convulsions to show whether or not they were manifestations of epilepsy, or whether they would be followed by or develop epilepsy later. Ten of the children showed spasmodophilia. In all these the convulsions ceased, but one of the babies became feeble-minded. It would seem that convulsions which occurred in babies with spasmodophilia and which were presumably manifestations of spasmodophilia were not likely to lead to the development of epilepsy later. In three instances the convulsions occurred in the course of whooping cough, and one of these children developed epilepsy later. Convulsions occurring in the course of whooping cough must, therefore, be regarded seriously. There were thirty-nine cases in which there was a single convulsion at the onset of some acute disease or with an attack of acute indigestion. Two of these children became epileptic and feeble-minded; a third had petit mal, and a fourth might or might not be epileptic. There were fifty-five cases in which there had been repeated convulsions during a considerable period, and in which there had been repeated attacks suggestive of petit mal. Taking seven years as an

arbitrary standard, only twenty-one of these could be considered normal at present. It has been impossible to tell from the nature of the early attacks as to the nature of the attacks when epilepsy develops later.

Epilepsy is far more likely to develop when the cause of the attacks is apparently an injury or severe labor, than when the apparent cause is a disturbance in the digestive tract. The longer the attacks have persisted, the more probable is the diagnosis of epilepsy. There is no way to determine immediately when a baby or child has a convulsion, or repeated convulsions, or repeated attacks suggesting petit mal, whether or not it has epilepsy or will develop it later.

DISCUSSION

DR. HENRY KOFLIK, New York: In the main I agree with Dr. Morse. Usually the application of the electrical test will determine whether or not a baby is a true spasmodophilic. In the vast majority of spasmodophilics, epilepsy does not occur later in life. One must be very cautious in making a diagnosis of epilepsy simply because a child has a few convulsions if the child is otherwise normal. It is well to remember that spasmodophilia may occur later in childhood. Unless there is a family history of epilepsy, one should be very careful about making a diagnosis of epilepsy during the early years of a child's life.

DR. L. R. DE BRYS, New Orleans: Would you group children who have spells of "holding the breath" as spasmodophilics? Have you met any children of that sort who have developed epilepsy later?

DR. J. P. CROZER GRIFFITH, Philadelphia: It is practically impossible early in life to make the diagnosis of epilepsy. In the new-born, convulsions may be due to birth trauma and this may result in epilepsy later. Convulsions due to indigestion are not likely to result in epilepsy.

DR. HENRY HEFMAN, New York: I have seen children develop spasms, coma and convulsions five or six days after birth. In such cases there may be a venous apoplexy due to injury at the time of birth, which has resulted in the blood oozing from the cortical area. In such a condition the results will depend on how much of the blood clot is absorbed and how much organizes. The early treatment of spasmodophilia may have an influence in the prevention of epilepsy.

DR. L. EMMETT HOEL, New York: Dr. Morse's conclusions are borne out by my experiences, namely, that a large number of children whom we expect to have epilepsy do not have it. The general practitioner and the neurologist are more likely to regard these children as prone to have epilepsy than is the pediatrician, because the pediatrician sees convulsions so often, and the great majority of the children who have had convulsions do not have epilepsy later. Recurring convulsions, with a sharp rise of temperature even if there is not much indigestion present, are not serious in relation to epilepsy; but when babies develop convulsions without a rise of temperature and without assignable cause, they should be regarded with suspicion. Dr. Morse's statement in regard to the relation of the convulsions of whooping cough to epilepsy were based on insufficient data. Unless there is some underlying peculiarity of the nervous system, epilepsy is not likely to follow the convulsions of whooping cough. One should be guarded in making a prognosis of epilepsy.

DR. SAMUEL S. AXAMS, Washington, D. C.: My conclusions on this subject are about the same as those of Dr. Morse. The most important point is to avoid casting the stigma of epilepsy on a child. In cases of convulsions during whooping cough, one should be cautious in making a diagnosis of epilepsy. Many of these cases of convulsions in childhood have some of the appearances of epilepsy; but I have always made it a point to teach my students to be very careful about calling them epilepsy. In some children the onset of an infectious disease is ushered in by convulsions, but after they have passed the period of infectious diseases, these children have no more convulsions.

DR. HENRY L. K. SHAW, Albany, N. Y.: There is a tendency among the laity to take the position "Once an epileptic, always an epileptic." I have had several children

with undoubted epilepsy who to all intents and purposes have recovered.

DR. HENRY F. HELMHOLTZ, Chicago: I would like to suggest the possibility that certain acute conditions, particularly gastro-intestinal disturbances, may be a factor in changing a latent spasmophilia into an active one. It seems to me that the main point to be emphasized is that if there is a rise of temperature at the onset of illness, convulsions associated with it are not of great importance so far as the diagnosis of epilepsy is concerned.

DR. FRITZ B. TALBOT, Boston: In considering this whole question the point should be emphasized that we are dealing with symptoms and not with a disease. If this symptom is due to spasmophilia, we would expect to find some change in the blood calcium. We have determined the blood calcium in a small number of spasmophilics and have found it lowered.

DR. J. L. MORSE, Boston: I have never considered breath holding as a symptom of spasmophilia. As to the birth hemorrhages, I have omitted all cases in which there were signs of injury to the brain. In a number of cases in which we have been asked to make a diagnosis as to whether or not epilepsy is present, if the convulsions have been present over a long period we make a lumbar puncture, a Wassermann test, examine the feces and urine, and give the child a thorough physical examination. We then follow up the cases in which we find nothing to account for the convulsions.

(To be continued)

AMERICAN GYNECOLOGICAL SOCIETY

*Forty-fourth Annual Meeting, held at Atlantic City, N. J.
June 11-17, 1919*

The President, DR. FRANKLIN H. MARTIN, Chicago,
in the Chair

Toxic Effect of Fibroid Tumors of Uterus

DR. R. R. HUGGINS, Pittsburgh: In the absence of other symptoms, it has been suggested that the absorption of toxins incident to the growth of fibroid tumors may account for certain changes in the heart muscles, which occur in many cases. The frequency of nervous symptoms, the relatively large number of cases of infection of the kidney secondary even to small fibroids, all point strongly in favor of such a theory. It is the consensus of opinion that heart changes are present in from 40 to 50 per cent. of the cases.

Complications of Uterine Myomas

DR. EDWARD E. MONTGOMERY, Philadelphia: Among the complications are nutritive disturbances. The enlarged and irregularly developed uterus, to accommodate itself to the contour of the pelvis, rotates on its vertical axis obstructing the return of blood through the veins, while the more rigid arteries continue to deliver the current. Edema and partial or complete necrosis may follow. Pregnancy may lead to such rapid growth of the tumor as to necessitate immediate resort to surgery. A subserous growth with pregnancy may be pressed between the developing uterus and the bony or parietal wall, arresting its circulation. On the right side, it simulates appendicitis. In one case it caused abortion and subsequently necessitated hysterectomy. Myomas encroaching on the uterine canal increase the danger of infection. Tubal infection, ovarian hematoma, pyuria and sacculated lobules are sometimes complications.

Study of Frozen Sections of Pelvis, with Description of an Operation for Pelvic Prolapse

DR. METTE BAILEY SPADING, San Francisco: The pelvis of a woman 32 years of age, a nullipara, was cut by frozen section into four segments. The surfaces of the segments were photographed and the pelvic fascia outlined. The uterus can be seen lying as in a swing by the paracervical tissue which is intimately attached to the pelvic fascia, the areolar tendency of which gives strong support to the bladder, vagina and rectum. The levator ani muscles and fascia give support from below and bring the lower part of the

vagina and rectum toward the symphysis. The operation I perform consists in dissecting free the fascia in the anterior vaginal wall to the arcus tendineus and overlapping, as described by Rawls. Amputation of the cervix is done, together with placing on either side of the cervix two deep sutures to control hemorrhage. The peritoneum is opened below the bladder and a subtotal vaginal hysterectomy is done, attaching the cervical stump to the sacro-uterine and severed broad ligaments. The round ligaments are drawn through the cervical canal and sutured on the vaginal surface. With rectal prolapse the rectum is supported by operations described by Ward, Studdiford and others.

Unique Diffuse Uterine Tumor: Adenomyoma with Stroma But No Glands

DR. DEWITT B. CASLER, Baltimore: A panhysterectomy and a right salpingo-oophorectomy were done on a woman 39 years of age for a supposed myoma of the uterus, and a metro-rhagia present for one year. The gross specimen was found to have a large, reddish polyp filling the cavity, while the walls of the uterus presented small, comedo-like masses, standing out prominently above the cut surface on pressure. Sections showed an almost total absence of uterine glands; but finger-like masses of interglutular stroma, dividing the uterine muscle into a fine meshwork, were seen extending as far as the peritoneal surface. Following this operation, the patient gave a history of regular menstruation, lasting one day each month for four years. At a second operation a cystic tumor of the left ovary was removed. This was found to contain many reddish polypi resembling in appearance the uterine specimen previously removed and made up almost entirely of uterine tissue, glands, stroma and apparently normal uterine mucous membrane.

Elective Cesarean Section

DR. EDWARD P. DAVIS, Philadelphia: Elective operation is justifiable only when the conditions present are such that any other procedure would be much more dangerous for mother and child. Elective section cannot be a frequent operation. It is justified in physiologic incompetence for labor, in some abnormal positions and presentations, in cases of repeated overgrowth of the child, and in cases in which previous labors have been dangerous.

Conservative Treatment in Certain Cases of Placenta Praevia

DR. GEORGE W. KOSMAK, New York: In the case of a primipara presenting a rigid and only slightly dilated cervix and the probability of a central placenta praevia, with the child at or near term and still in good condition, the amount of bleeding not having been extreme, there is no question that abdominal cesarean section offers the best method of delivery for both mother and fetus. The large majority of cases are outside of this group, however; only a portion of the placenta impinges on the region of the internal os or the lower uterine segment, so that hemorrhage of any extent results only after the cervix has become thoroughly softened and is dilated. Nevertheless, even in this group the amount of bleeding may be sudden and excessive, especially as the lower uterine segment in multiparas, in whom we most often find this abnormality, is thoroughly softened and separated easily from the placenta.

Control of the hemorrhage during the process of dilatation remains the important indication, and this can be made most effectively by the extra-ovular introduction of the bag, a method described and adopted by Dr. E. B. Cragin. As an emergency measure, it is much superior to the intra-ovular introduction of the bag because less harm is done by hospital interns, for example, than if the perforation of the placenta with a Braxton-Hicks version or intra-ovular introduction of the bag is carried out.

Premature Separation of Normally Implanted Placenta

DR. ARTHUR H. MORSE, New Haven, Conn.: Ligation of the uterine veins in pregnant rabbits reproduces lesions in the uterus identical with those in women suffering from premature separation of the placenta. Similar lesions in rabbits result from constriction of the vessels when the uterine

horn is rotated. Premature separation of the placenta in women also probably depends on an acute disturbance of the uterine circulation.

Nutrition of Fetus

DR. J. MORRIS SLEMONS, New Haven, Conn.: No diet is specifically adapted to the state of pregnancy; the prospective mother may exercise the same freedom in the selection of food as any one else. She should select what will agree with her and avoid that which she cannot digest and assimilate. In the main, personal experience must guide every one as to what to eat, and most women follow the dictates of appetite as safely after they become pregnant as they did before.

Value of Repeated Small Blood Transfusions in Blood Stream Infections

DR. JOHN OSBORN POLAK, Brooklyn: After the bacteria have gained entrance to the blood stream, the cellular elements of the blood are rapidly destroyed. The heart, liver, spleen and kidneys show definite pathology, and acidosis develops. Small repeated blood transfusions increase the cellular elements, stimulate resistance and raise the blood pressure, hence adding to the natural defense.

Age Distribution and Age Incidence in Cancer of Uterus

DR. REUBEN PETERSON, Ann Arbor, Mich.: Between the ages of 35 and 65 occurs 82 per cent. of uterine cancer. Uterine carcinoma below the age of 20 is exceedingly rare, but it does occur in an appreciable percentage of persons between 20 and 25. Adenocarcinoma of the fundus is not a disease of early life, there being in my series only three women out of ninety-four below the age of 35. From 10 to 15 per cent. of uterine carcinomas are located in the fundus. In contradistinction to carcinoma of the fundus, 23.5 per cent. of squamous cell carcinoma of the cervix is found in patients under 40. Practically 50 per cent. of 369 cases of squamous cell carcinoma of the cervix occurred between the ages of 40 and 55. The maximum age incidence for carcinoma of the uterus is at age period 55 to 60; it declines rapidly from this age period to the period 70 to 75. After each age period of greatest carcinoma incidence is reached there is a sharp decrease in incidence, demonstrating the incorrectness of the statement that the age incidence of carcinoma increases with the age period.

Radium Treatment of Uterine Cancer

DR. HAROLD BAILEY, New York: Practically all cases that have a complete radiation of the local lesion and the lymphatic and other involved tissue in the parametrium, pass through a period of improvement. In all but the more advanced conditions this improvement consists of a disappearance of the ulceration, a lessening or entire disappearance of the discharge, a gain in weight, and general improvement of health.

After a longer or shorter time of well-being following the treatment, many patients have further development of cancerous tissue behind the vault of the vagina. In the effort to save these patients that have a retrogression after six or eight months, I have pushed the radium treatment of the parametrium, both by vaginal and by surface radiation, to the highest limits of safety, and have thereby caused in many who now appear to be free from cancer various types of pelvic sclerosis, both mild and severe. I have felt that it was wise to recede somewhat from the massive dose given by the bomb applicator. This dose now is actually in the neighborhood of three fourths of the maximum. The method in use permits of the entire treatment being given in a forty-eight-hour period, and with only moderate discomfort to the patient. The local slough and signs of irritation in the vault of the vagina, seen so frequently in using the older method, are now lacking in most of the cases. From our results in the uterine body cancers, it would appear to be necessary to remove the uterus after a preliminary radiation, or when this is inadvisable to radiate the entire pelvis as completely as is done with a cervical tumor. The results in cases of recurrent cancer following a hysterectomy are very promising. It should be understood that it is as important

to radiate these cases immediately after operation as to operate early in the course of the disease. Surgery has been the palliation from the radium that it may be said that no uterine cancer case receives proper treatment without thorough radiation of the tissues of the pelvis.

Tumors of Bladder in Women: Diagnosis and Treatment

DR. HOWARD A. KELLY, Baltimore: It is very important to utilize the natural landmarks as well as an artificial divider into hemispheres. Using the end of the sigmoid as a measure and these landmarks, the first step is to plot out all areas of disease and note them on a simple chart. Malignancy in bladder tumors is not always to be determined from the microscopic standpoint. Some tumors which are classified as malignant by the pathologist are clinically benign and vice versa. An ulcerated and infiltrated base is the clinical test of malignancy. The treatment is occasionally by excision, but, as a rule, by fulguration and radium. Many patients have apparently been cured, even those who have tumors which are malignant and infiltrative.

Are the Operative Procedures Done for Dysmenorrhea and Sterility Justifiable in the Light of Developmental Study?

DR. FREDERICK C. HOLDEN, Brooklyn: Operative procedures alone give a small percentage of successes and sometimes add a troublesome pathologic condition of the genital organs to the syndrome of dysmenorrhea and sterility. The only intelligent method of studying the activity of the spermatozoa is in their relation to the female secretions. Further experience with endocrines will tend to clarify our present position in regard to the treatment of dysmenorrhea and sterility.

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS

Eleventh Triennial Session, held at Atlantic City, N. J., June 16 and 17, 1919.

The President, DR. SIMON FLEXNER, New York, in the Chair

The Surgical Aspects of Reconstruction

DR. JOHN M. T. FINNEY, Baltimore: Surgical reconstruction comes under three main heads: (1) prophylaxis, (2) plastic and reconstructive measures, and (3) prostheses. Two classes of cases will in future be noted, the unfortunate class, the "unpreventable deformities," the irreducible minimum, that, owing to nature of injury, loss of substance, etc., will remain as an unavoidable consequence of war; and the "preventable deformities." Such cases include deformities and disabilities from malunited fractures, osteomyelitis from neglected infections, paralysis from divided nerves (possibly due to unwise debridement), contractures from scar tissue, etc. In modern warfare a small percentage of fatal casualties must result; a much larger number of cases of complete recoveries will be found, and the balance of injuries will result in more or less permanent disability, these latter varying with the circumstances under which they were received and the treatment administered.

A point of great importance is the part played by transportation in modern warfare. If the ambulance can deliver the patients promptly and in good condition to the surgeons in the rear, the surgeon has to deal only with the trauma presented; if, however, delay occurs in receiving the wounded the problem then is primarily one of infection and is infinitely more serious.

In Lyons, in 1914, the first actual training school for invalid soldiers was established, although sporadic attempts had previously been made in Belgium, Russia, Great Britain, and France. This idea gained favor rapidly and has developed to such an extent that now the disabled soldier has the opportunity to again become an independent, self-supporting member of society. Prevention is better than a cure. The military surgeon has two very distinct duties: (1) to recognize, or prevent, if possible, deformity and disability; (2) to return the disabled soldier to the line in the shortest possible

time. In the early days of the war attention to proper shoeing and the building up of men so as to overcome minor ailments were important points in relieving the hospitals of many cases; and much material was thus early reconstructed and added to the man power of the army. Proper standardization and application of splints was found also to be an enormous factor in saving loss of life and preventing disability.

The venereal disease problem, which at first bid fair to be a very large factor in loss of man power, was dealt with in characteristic American fashion, in spite of opposition of the French (and, to some extent, the British). The prevention of waste of efficiency was an end to which all strove, and the establishment of surgical laboratories, where courses in life saving, blood transfusion, and the physiology and treatment of shock were offered, was a powerful means to this end. Shock teams, composed of physicians and even dentists, were used to economize the services of surgeons.

The number of incapacitated from the war have been great, but they are small compared with the constant stream of injured constantly pouring forth from the myriad of industrial establishments throughout the world, and methods to make the experiences of the war apply to the salvage of civilians are already being considered. The early inauguration of reeducational measures, the maintenance of a stimulating environment, the determination of the man's fitness for any given vocation must be given due consideration. The economic value of not over filling certain trades, and the limited demand for certain kinds of labor should be taken into account. The training of our disabled is simply a means to an end, the end being to equip men for their whole future, to make them self-supporting, self-respecting citizens, capable of rendering continuous service for the rest of their lives. Society is under a moral obligation to provide suitable employment of a permanent character. Reeducation courses may be given in a variety of ways and places, in hospital centers and convalescent homes, technical schools and colleges, agricultural institutions, private workshops and factories.

The Neurologic Aspects of Reconstruction

DR. HARVEY CUSHING, Boston: Reconstruction, like conservation, is a useful word, but it may be greatly overworked and it should include later treatment. The question of reconstruction is involved in what our hospitals are attempting to do for their patients. We see the same defects in civilian hospital results, especially in regard to the difficult by paths of medicine which deal with psychology. Less is known of the disorders of the nervous system than of any other part of the body. The mental hygienist and the neurologist have raised a small voice which has been lost in the general uproar of reconstruction. The stress of life falls heaviest on the central nervous system, and in times of war this strain is increased; yet we must remember that in war time sane minds are even more necessary than sound bodies. An effort was made during the draft to comb out the neuro-pathics, but in spite of this many were left who developed neuroses in the camps, and later in the field the numbers were added to, by means of subjection to the strain of high explosives. It was recognized that nervous disorders would represent the final sediment of war injuries, and those most difficult to treat. Thus, in 1918, a neurologic force was organized with a neurosurgical consultant. No figures are ready as yet, except comparative ones compiled by the French, who compute that 25 per cent. of war disabilities represent neurologic problems. Cranial injuries represent 16 per cent. of battle wounds, being caused in the early days of the war by high explosives, and later by machine gun injuries. Patients with craniocerebral injuries did not stand transportation well, and special centers for their treatment had to be devised near the combat area.

In time of war the registration and evacuation of the wounded are paramount problems; research does not thrive within the sound of battle and follow up studies were difficult. If notes were sent on, they rarely reached their destination. Just as there were men in the lines who had never fired a rifle, there were surgeons in the service who had never seen a war wound, but an effort was made to secure for each

hospital one neurosurgical team. Although some attempts at proper distribution of cases have been made, on the whole, there has been a distinct failure to place special cases where ability to treat them is available. Organization in this respect is falling lamentably short of its opportunities.

The Work of Physical Reconstruction as it Concerns Orthopedic Surgery

DR. JOEL E. GOLITHWAITE, Boston: Orthopedic surgery stands primarily for preservation of function in injured or diseased parts, or for restoration of function in parts which have been previously injured or diseased. In England Sir Robert Jones was assigned to the care of these cases. It was found necessary that the functional reconstruction work should be carried far forward, in fact right up to the trenches. Thus responsibility was assumed for the care of the individual as soon as the injury was received. Orthopedic surgery was developed in conjunction with general surgery to avoid overlapping of effort. The work of the orthopedic surgeon in the early months of the war consisted largely in training recruits so that elements of weakness and strain would be eliminated. Careful training and principles of posture were instilled, with training by squad drill, bayonet drill, route marching and rest or play periods interposed. Men with painful feet were taught to stand straighter, to carry themselves more springily, and in extreme flatfoot cases the raising of the heel of the shoe and the use of the figure of eight ankle strap was used with great success. Foot plates were not used at all in the A. E. F.

The treatment of actual disease and injury was planned from the beginning with the ultimate result in mind, so that as little as possible of loss of tissue, and as much of ultimate function should ensue. Many times the original injury caused little general shock, and as long as the man lay on the battle field he was in good general condition and could easily have stood operation. The jar of removing him 2 or 3 miles to a dressing station was often so great that shock occurred, and even death, before the station was reached. If, therefore, the man could be splinted properly before he was moved at all, he could be transported without shock or harm. Splints were standardized by a special board in the summer of 1917, and eight selected types were chosen in regard to their simplicity and efficiency. Medical officers and stretcher bearers were instructed in the use of these splints so as to apply them with the greatest possible advantage. The mortality previous to the battle of Arras in getting the wounded to the rear was sometimes as high as 80 per cent. With nothing more than the proper standardization and application of splinting, this figure was brought down to 30 per cent. So efficient did the stretcher bearers become in the application of splints that many of them were able to apply the Thomas traction splint in two minutes.

Transportation thus became a satisfactory procedure and in many cases of long sluggish infection, the vibration of the train stimulated circulation and improved the general condition, aided perhaps by the psychic stimulus to the soldier of being directed towards home. Splinting has not only been of use in transportation, but in the preservation of position while early attempts at movement of the part were started. This was especially true in the difficult cases of gun shot wounds of the hand. Proper splinting of the parts has enabled these men to get at work, either in the wards or workshop, so that not only has healing of the wound been hastened, but atrophy prevented and functional restoration been obtained in a minimum of time. The great increase in the number of wounded and consequent overcrowding of hospitals in France, made it essential that many men be transported overseas to be cared for in this country. Few, if any, men have been harmed by transportation, and many are living today because of the stimulus of the thought of homecoming. There is no doubt that the trained orthopedic surgeon found an important place in the army organization. The ultimate test put by the army was that of function. The corrective workshop, the employment of bedside occupations have all had their places in functional development. The employment of reconstruction aides, not only in remote rear hospitals, but with the army at the front, shows the develop-

ment of the idea of functional reconstruction. Occupational therapy has come to be recognized as of as much importance in certain stages of the individual's recovery, as nursing, or any other detail of medical or surgical care.

DISCUSSION

DR. DEAN D. LEWIS, Chicago: At the beginning of the war we were accustomed to regard these different units as separate and distinct. The evacuation hospital did the gross surgery and then sent the man back to the base; then he could either be sent further back, or else be returned to his division. Reconstructive surgery was thought of as reserved for the general hospitals at home. That was a false idea; reconstructive surgery should begin as far forward as possible and the place for the consultant is at the evacuation hospital. His services must not be wasted as those of a transportation agent, but he must be an operating surgeon with a staff under his absolute control. The war has taught us much about the treatment of injuries in civil life; osteomyelitis could often have been avoided if debridement had been done more widely. Another point is that we must have sufficient soft parts to fill the gaps. How long shall these men stay in hospital? They must stay there until they have received their maximal degree of improvement, and until they are fitted to make a living for themselves.

DR. NATHANIEL ALLISON, St. Louis: The surgery of the forward area of the army gave us several very useful lessons for civil surgery. If it is possible to prevent shock by proper splinting of fractures, this is one of the lessons we have to carry to civil life. We soon realized that there was less shock in the ordinary fracture if the man was splinted where he was injured. Men were apt to die from shock in the front area, and this was especially true in cases of fractured femur. We found that by pushing the Thomas splint as far to the front area as possible we did more to prevent shock than by any other means. Damage done to muscles and vessels by fragments of bone, and also pain, were very much lessened. We used to teach the stretcher bearers three things: proper splinting to fix the part; the use of dressings to stop loss of blood, and the necessity of a blanket to keep the patient warm. We very rarely used the tourniquet to stop hemorrhage. We can apply these principles to civil life with great advantage. Another interesting observation was that shock was lessened by reassurance. The wounded man when he was picked up was either frightened, or he was very angry, usually the latter. The mental state was improved and quieted by reassurance. We gave the man a hot drink, the proper splint was applied, the hemorrhage was controlled, and a warm cover given. Under these conditions shock usually did not manifest itself.

DR. GEORGE E. BREWER, New York. In regard to the prevention of shock: There is absolutely no question but that the proper and timely application of splints, as soon as possible after the wound is received, is essential, particularly so in cases of fractures of the long bones and compound fractures associated with laceration. This one factor did more to prevent shock than anything else. It is to the everlasting credit of the American Army corps that it was insisted on from the very beginning that the Sanitary Corps men should be trained to apply splints to give the maximal amount of protection.

The Medical Aspects of Reconstruction

DR. J. W. S. THAYER, Baltimore: Apart from the fundamental question of diagnosis the medical man finds himself confronted with two problems: (1) that of prophylaxis and (2) his duty to the patient during convalescence. In war time the value of convalescent care is put on its proper basis, in the reconstruction program. Most of the men treated medically clamored to be sent back to their organization; once hospitalized the men quickly lost morale, discipline and physical vigor, and many, especially the gassed cases, even developed psychoneuroses in the war hospitals, therefore it was found necessary to keep them as near the front as possible, to keep them from falling under the influence and surroundings of hospitalization.

The treatment of convalescents was carried on in camps, under expert training and physical supervision. A modified

physical regime was adopted for the men under military status. Work, play, rest, recreation and amusements were all put into use as part of the general scheme. It was found that the psychic element was of importance, for those men who tired soon at drilling, could endure much more exertion in games. Classes were graded as to exercise and drill and the men supervised by an officer who had special cardiovascular training. This work was especially adapted to that class of cases known as effort syndrome. Often as many as 99 per cent. of these men were returned to duty. An endeavor was made in these camps to determine the average time needed for complete convalescence from infectious diseases.

Many of the men who were gassed or exhausted were sent to rest camps and replacement depots, where they recuperated and were returned to their divisions. Measures for the treatment of tuberculous soldiers were necessarily carried out in this country, where large sanatoriums have been established in suitable localities and the disease can be combated under the best possible conditions, with necessary hygienic and dietetic regime. War statistics in regard to the duration of convalescence have shown the need of convalescent departments in connection with large hospitals, in which every arrangement for the well-considered rehabilitation, mental and physical, of the convalescent, may be carried out. In this country the admirable arrangements in effect at General Hospital No. 9 at Lakewood, N. J., have demonstrated what systematic physical and mental training can do for that large body of individuals who are slightly below par.

Cardiac Phase of the War Neuroses

DR. A. E. COHN, New York: In 1871, Da Costa of Philadelphia described what he termed irritable heart of soldiers, which is identical with what has been observed in the present war. Da Costa included heavy acoustrements as a contributing factor. All observers have agreed as to the large numbers of these cases, called D. A. H. (disordered action of the heart) by the British. The circulatory derangement, however, provides opportunity for differences in interpretation of the phenomena. The latter may be observed in varying states, such as, for example, chronic cardiac disease, acute infectious diseases, hyperthyroidism or associated with the neuroses. Before the present war, owing largely to the influence of Da Costa, these cases were considered as being related to cardiovascular disease. There is no organic functional disease, however, and it remains to establish a connection between these symptoms and the neuroses. Patients usually present those states classed as anxiety neuroses and psychiatrists have interpreted them as cardiac manifestations of neurotic character. The relation of "anxiety states" to war is abundantly clear. Anticipation of its terrors was awakened in every recruit. The sights and sounds of actual warfare wore down the resistance of the most enduring. The constitutionally predisposed fell out here first. Those with slightly better endurance fell out in France. On the whole, those who reached France were superior. Another important point, indicating a neurotic origin, was that these symptoms were unknown in the severely wounded, those whose faces were turned away from the front. This was true of severely gassed and of prisoners of war. These men had done with war.

The prognosis of these conditions depends on their origin. If they are thyroid in nature, or dependent on cardiac abnormality, they will be identified with these conditions. If they are neurotic, suitable treatment will re-establish them. They may, however, if returned to the front, retard the work of their organization.

Treatment also depends on diagnosis. Da Costa put them to bed and treated them with drines. This was not found beneficial in the present war. The system of Lewis—graduated exercise—was of signal benefit. Exercises by the drill sergeant, however, did not meet the needs of the situation, strength, in these cases, being a neurologic and not muscular function. The experience of the British in the treatment of these cases was made use of by the A. E. F. It was found that the convalescent camps should be separated from hospitals, by several miles. The camp atmosphere had to be

attractive, with well designed and landscaped grounds. The soldiers were kept on modified but strict discipline. They were instructed and taught to amuse themselves. This experience has an important application to civil life, where large numbers of these subnormal persons are to be met.

Reconstruction in Nervous and Mental Disease

DR. PEARCE BAILEY, New York: This question of the control of nervous and mental disease has an important bearing on the health of the whole community. The war has taught us that these patients will be constantly returning to us unless necessary steps are taken to handle their cases. There is no machinery at present in this country which undertakes to provide for their care; very many of them no doubt have become adjusted to their original environment and are pretty much as they were before, but a very large number need special treatment. It is a problem of civil, rather than of military reconstruction. At least 72,000 young men of this type were rejected for service. Thus there is an enormous field in preventive medicine awaiting the neuropsychiatrist. The fact that such a vast number of young men have been found unfit to carry out their duties as social units, has a very serious social significance.

The army has done harm to this large proportion of people by taking them out of the adjustment they had formed for themselves in civil life. Army life does not build up neurotics and the potentially insane are apt to go insane all the quicker when subjected to its stress. Psychoneurotic states formed a higher percentage in army than in civil life. Perhaps among the causes that contributed most to the breakdown of the nervously unstable, separation from home was the chief factor. It was also somewhat of a paradox that cases that would have been considered most serious at home recovered more rapidly under military life. Restraint with these persons was found to be entirely unnecessary.

The care of the insane is really a civil problem. We must extend our system of state hospital mental clinics. These constitute a real prophylactic measure and they will be of use to the discharged soldiers who still need some mental help and supervision. The treatment of chronic or inveterate military cases was a distinct reconstructive problem.

The starting point in civil life in regard to reconstruction is without doubt in the schools. We can reclaim the school child, but the adult inmates of institutions we cannot reclaim. The educational departments of our states and municipalities are the most promising basis for a system of control of the menace of nervous and mental disease and criminality. They cannot be so constituted, however, unless the medical profession supervises their problems and supplies competent advisers and workers. We shall never get anywhere unless the medical profession stands behind this movement more heartily than it has done. We must be better represented in the neurologic work in our hospitals and a separate research institute is an essential need. The establishment of an independent foundation seems to be more or less a sine qua non for the firmer, broader and more scientific grasp of these subjects.

DISCUSSION

DR. FRANCIS W. PEARBODY, Boston: Dr. Cohn gave us a very clear account of the "irritable heart of soldiers." We used the results of his observation in France and combined them with our experience in General Hospital No. 9, in Lakewood, N. J., where there were excellent facilities for clinical investigation. We were interested to find that a large percentage of these men, apparently highly neurotic, were particularly sensitive to small doses of epinephrin. This would point to a hypersensitiveness of the sympathetic autonomic nervous system, but we do not know what the relation of cause and effect may be between this and the neurotic constitution. Two types of individuals were seen at Lakewood: (1) the normal individual who had broken down under the military stress; (2) constitutionally inferior individuals, in whom the symptoms were latent over a very long period of years, often dating back to childhood. This constituted the most important group. These men were not really a product of the war, but they became prominent when they entered into army life. There was an inherited nervous taint. Most

of them were apt to regard themselves as being "not strong" or as having a "weak heart." In the army they broke down with the signs and symptoms of physical invalidism, partly from physical strain, but chiefly because they were unable to adapt themselves to the conditions of army life. In this particular group we noticed an actual decrease in strength of the skeletal muscles. Fifty per cent. were below normal. Graded physical exercise was important and it was found possible to double the actual physical strength of these men while there was also a considerable psychologic effect. Many of these men have gone back into civil life and are able to take their place as useful economic units, whether they were good soldiers or not.

The Physical and Mental Rehabilitation of Disabled Soldiers of the United States Army

DR. FRANK BILLINGS, Chicago: The policy of physical reconstruction of disabled soldiers, later extended to disabled sailors and marines, was formulated in the office of the Surgeon-General in August, 1917. It was applied in seven hospitals early in 1918, and finally was approved by the War Department, July 29, 1918. This work is defined as continued treatment, carried to the fullest degree of maximum physical and functional restoration, consistent with the nature of the disability. To this end all known measures of modern medical and surgical management are applied. The educational program was important and comprehensive, embracing courses in technical, agricultural and commercial subjects. Many disabled soldiers who were qualified aided in the training of their fellow patients. Civilian women worked as reconstruction aides in giving courses in the arts and crafts and commercial studies. A director of sports, games, gymnastics and military drill supervised these branches, in cooperation with the American Red Cross, Y. M. C. A., K. of C., Jewish Welfare Board and Salvation Army. Special buildings, gardens and fields have been utilized for the purpose of training convalescents in workshop and academic courses and in agricultural pursuits. Equipment for shops, schools, physiotherapy, and gymnasiums has been supplied. Needful books have been furnished by the American Library Association.

Before the armistice was signed, approximately 10,000 disabled soldiers were returned from the A. E. F. to the United States. Following the armistice, the return of sick and injured was expedited, and from Nov. 11, 1918, to June 1, 1919, approximately 140,000 disabled soldiers have been returned to America. This naturally required additional hospitalization, and at the height of the influx, forty-seven reconstruction hospitals were functioning. At the present time forty-four general and base hospitals are carrying on this type of treatment. After July 1, 1919, the work of physical reconstruction will be concentrated in nineteen centers. The work of the educational personnel has been increased to meet the need. Since the armistice has been signed convalescent camps have been established in various parts of the country and soldiers have been sent to the centers nearest their homes. Here they have received the final hardening and curative processes by means of setting-up exercise and military drill. The number of men so trained since the signing of the armistice totals 47,858 to the present date.

In spite of almost insurmountable difficulties it is believed that physical reconstruction of the soldier has been of the greatest value in maintaining discipline; promotion of morale; the diversion of the soldier's mind from his disability; the arousing of his interest in education which would overcome his handicap; and the physical and functional restoration of the patient. Often the patients have been enabled to take up a more lucrative profession than that which they held formerly and the men have been stimulated to take further training with the federal vocational board, after discharge from the army. This board has been actively cooperating all along in giving the necessary vocational guidance. The establishment of the measures of physical reconstruction in the treatment of disabled soldiers has been so beneficial that it will create a demand for the application of like measures in the treatment of patients in civilian hospitals in the country.

Digitalis Therapy.—A great deal of nonsense, in Christian's opinion, is written about digitalis that does not upset the stomach, and much effort appears to be used by pharmaceutical houses to prepare such forms of digitalis. Most of them do not cause nausea, he says, because they are weak forms of digitalis. The fad of fat-free digitalis is an excellent example of this wasted energy. Were this effort directed toward securing a potent active leaf, without which no good digitalis preparation is possible, far better results would obtain. The powdered leaf made freshly into pills is as satisfactory a form of digitalis as either tincture or infusion, and if the leaf is good, it is just as effective as digipuratum and digitidin, and far less expensive. Digitalis should be prescribed in weighed or measured amount, not by drops, and enough should be given of a reliable preparation (that means a good leaf as the starting point of the preparation) to produce a definite effect at least within four days; usually an effect is noted to begin in half this time. In Christian's experience in chronic myocarditis, most excellent results follow an adequate digitalis therapeutics, and there are no contraindications to its use, for even in those cases advanced beyond the bound of a therapeutic response no bad effects follow digitalis. Aortic insufficiency does not contraindicate digitalis and very excellent results follow the use of digitalis in hearts that are not fibrillating. Christian's observations confirm the findings of Mackenzie and Cohn and Fraser that the drug rarely slows the pulse, except in auricular fibrillation, until toxic symptoms are produced. He has frequently seen good results in chronic cardiac cases with edema in which there was no irregularity of the pulse or only an occasional extrasystole. Cases are cited.

Epidemic of Typhoid at Hot Springs, N. C.—A very complete analysis of these cases was made by Dunham. Four of the fifteen deaths (8.06 per cent. mortality) were caused by perforation. Pulmonary involvement was the terminal process in six cases. Incontinence of stool and urine occurred in thirty-five patients. Intestinal hemorrhage occurred to a marked degree in twenty-five patients, though blood was present in the stools in many more instances. The most interesting feature in the study of this epidemic arose in the diagnosis of six perforations. Not one case presented the classical symptom of sudden paroxysmal abdominal pain. Vomiting did not occur in any of the cases. One case presented the only incidence of appendicitis. Cholecystitis was a complication in three cases. Bronchitis was observed so frequently that this phenomenon may not be considered a complication but a most frequent symptom. Typhoid vaccination was given in many cases during the incubation period of the disease. The medical attendants were unable to observe any amelioration of the symptoms among such patients.

Tests of Functional Capacity of Circulation.—Comparative functional tests of the circulation were made at Camp Ziegler by Taylor in 233 cases, including the normal, the various tachycardias, sinus bradycardia, thyrotoxic conditions, neurocirculatory asthenia, etc. The characteristic finding in sinus tachycardia, in compensated mitral regurgitation and in sinus bradycardia, was the absence of any effect on or only very slight increase of the pulse rate after exercise. In thyrotoxic heart the characteristic effects were marked instability of the pulse rate, with great increase after exercise associated with an instability of the diastolic blood pressure. A similar effect, but less marked, was found in neurocirculatory asthenia. In the latter condition it was noted that the thrill disappears when the relationship of apex beat to chest wall is disturbed or distorted on auscultation. The tremogram is recorded as a differential point between neurocirculatory asthenia and thyrotoxic conditions. Hypertonicity of the heart muscle is the physiologic basis of the cardiac signs in neurocirculatory asthenia. Thyrotoxic conditions and nephritic hypertension lessen the functional circulatory capacity. Aortic regurgitation and congenital heart lesions gave fairly distinct features, but further studies along the lines indicated are suggested to establish the results in congenital heart.

Impairment in Mitral Stenosis. The association of pulmonary signs in mitral stenosis, Goodman says, occurs frequently. Snappy quality of the first sound and systolic tap or shock on palpation, absence of hypertrophy of the left ventricle in the cases uncomplicated with insufficiency, presystolic thrill, presystolic murmur and accentuation of the second pulmonic sound establish the diagnosis. The history of rheumatic fever, chorea, tonsillitis and growing pains, when authentic, is an added evidence. Goodman urges that examination for these features should be made with the patient erect, recumbent (not omitting the examination with the patient lying on the abdomen) and before and after exercise test. Murmurs may be missed when the patient is erect and with the heart at rest, and may be very clearly heard when recumbent and with the heart beating more forcefully, as after exertion. Twenty-seven cases are cited by the author.

Blood Creatinin in Nephritis.—Observations on 100 cases of nephritis showing creatinin retention are recorded by Myers and Killian. Of these 100 patients, eighty-five had a creatinin content of over 5 mg. per hundred c.c. of blood, the figures ranging from 5.1 to 33.3 mg.; eighty of these eighty-five patients have died. Of the five remaining the condition of three is essentially unchanged, while two have recovered. These two patients showed only a temporary elevation of the blood creatinin. A considerable number of the eighty-five patients were able to be up and about and some showed decided clinical improvement. According to the authors the creatinin gave a better prognostic insight into these cases than either the blood urea or phenyl-sulphone-phthalein tests, which were made simultaneously. It is their opinion that in advanced cases of nephritis the blood creatinin furnishes a more reliable prognosis than any other test.

Case of Symptomatic. S. Chelliah, Columbia College—p. 796.

Clinical Diagnosis of Ectopic Pregnancy. Out of 100 cases of specimens of tubes or adnexa removed after a clinical diagnosis of ectopic pregnancy and examined microscopically

septicly by Caturani, only fifteen failed to produce positive microscopic evidence. The rupture of the tubes, ragged in appearance, typical of the erosion of the chorionic cells, is almost pathognomonic of ectopic pregnancy. In forty-two cases of rupture, only one was negative.

Analysis of Ectopic Gestation.—From Farrar's study of these cases it appears that infection or mechanical alteration due to adhesions of the fallopian tube predisposes to ectopic gestation. The onset of symptoms or an acute attack occurs equally as often at the time of an expected period, or just after a normal period as it does when a period is overdue. Pain with, or without, bleeding is present in every case of ectopic gestation unless unruptured. Tearing, lancinating pain is not as common in ectopic gestation as pain of a cramplike or bearing-down character. Unusual, one-sided pelvic pain when associated with evidences of peritoneal irritation and fainting warrant the diagnosis of ectopic gestation.

Differentiation of Early Tuberculosis and Hyperthyroidism by Epinephrin Test.—To support their contention, which is, that hyperthyroidism is responsible for the general symptoms usually attributed to tuberculosis in most of the cases where the presence of clinical tuberculosis is questionable and also where the tuberculous lesion is thought to be insufficiently active to account for the severity of the symptoms, Nicholson and Goetsch applied the epinephrin test, at first, to those patients in whom the diagnosis of tuberculosis was questionable, and later as a routine measure to all patients entering the Trudeau Sanatorium. Positive results in support of this view have been obtained. Of the eighteen cases belonging to the "clinical tuberculosis questionable" group, there were ten which reacted positively to the test, and eight which showed an entirely negative reaction. Out of sixteen "clinical tuberculosis inactive" cases, nine showed a positive response to the test. Of six cases in which there was a definitely but moderately active clinical tuberculosis, the reaction was negative in all.

Treatment of Duodenal Ulcer. The dietary treatment of duodenal ulcer is divided into five periods by Foxworthy: The nutrient enema period lasting from four to seven

days. This should be begun at once, following diagnosis, or following hemorrhage. 2. The liquid, or albumin water period, from one to two weeks, commencing with the whites of two eggs in water, every three hours, and increasing gradually. Cream is used when eggs do not agree. 3. The semiliquid period, one week, in which the regular feedings of albumin water are kept up, substituting for certain feedings such food as creamed toast, potato soup, or purees. 4. The semisolid period, lasting one week, which is a prolongation of the semiliquid period, during which oatmeal, mashed potatoes, tapioca, custards, soft boiled or soft poached eggs are added to the dietary. During this period, the albumin water may be withdrawn safely, although at any indication of recurrence, the diet should drop back to the diet of the second period—all albumin water only. 5. The solid food period, broiled meat patties, the meat ground very fine, and lean meat only, squash, breast of chicken, minced, following which the patient should be able to take the ordinary prescribed diet for ambulatory ulcer patients, which is a maximum of albumins and a minimum of starches and sugars.

Experimental Production in Dogs of Emphysema with Associated Asthmatic Syndrome by Means of Intratracheal Ball Valve. W. H. Harris and E. P. Chillingworth, New Orleans.—p. 75.

Etiology of Yellow Fever. IV.—The majority of guinea-pigs inoculated by Noguchi with the blood of yellow fever patients escaped a fatal infection. There were a number of instances in which the inoculation of yellow fever blood induced in these animals a temporary febrile reaction on the fourth or fifth day, followed in some cases by slight jaundice, but with a rapid return to normal. Most of these guinea-pigs when later inoculated with an organ emulsion of a passage strain of *Leptospira icteroides* resisted the infection. On the other hand, the animals which had previously been inoculated with the blood of malaria patients or normal guinea-pigs died of the typical experimental infection after being inoculated with the infectious organ emulsion.

Etiology of Yellow Fever. V.—The serum from a number of persons recovering from yellow fever in Guayaquil was studied by Noguchi with a strain of *Leptospira icteroides* derived from one of the yellow fever patients with a view to establishing its possible immunologic relationship. For this purpose the serum of convalescents was mixed either with an organ emulsion of a passage strain, or with a culture of the organism, and inoculated intraperitoneally into guinea-pigs. The Pfeiffer reaction was first studied, and then the animals were allowed to live until the controls, inoculated with the same emulsion or culture of *Leptospira icteroides* but without the serum, or with serum from patients suffering from other diseases than yellow fever, had died of the experimental infection with typical symptoms. A positive Pfeiffer phenomenon was observed in fifteen of the eighteen convalescent cases studied, or approximately 83 per cent. Serums from ten nonimmune soldiers and from two malaria patients gave uniformly negative results. Protection from an ultimate fatal infection was afforded some of the guinea-pigs which received the serum of yellow fever convalescents,

while the control animals succumbed to the infection with typical symptoms. In one instance, in which the serum was tested on the second and the tenth days of disease, a Pfeiffer reaction was demonstrated, as well as protective property against the infection, in the specimen from the tenth but not in that from the second day. From these observations of immunity reactions Noguchi concludes that it appears highly probable that *Leptospira icteroides* is etiologically related to yellow fever.

Etiology of Yellow Fever. VI.—On three occasions, that is, from three out of eleven cases of yellow fever, the *Leptospira icteroides* was directly cultivated by Noguchi. These three strains were found to induce the characteristic symptoms and lesions when tested on guinea-pigs. *Leptospira icteroides* was also obtained in pure culture from the blood of guinea-pigs which succumbed to infection after being inoculated with the blood or organ emulsions from patients suffering from yellow fever. These cultures also proved to be virulent when tested on susceptible animals. The morphologic characteristics and biologic properties of the organism are described in detail.

Growth Accessory Substances for Bacteria.—Kligler reports experiments bearing on (a) the effect of vitamins on the growth of a number of organisms pathogenic for man; (b) the distribution of these substances in animal tissues; and (c) the relative significance of the fat soluble A and water soluble B in the cultivation of these micro-organisms. At present there are few data bearing on these questions in relation to bacteria. Beef heart, goat's blood, rabbit and cat tissues, and human secretions were used. The effect of these extracts was tested by adding graded amounts to nutrient broth or agar, or to phosphate peptone agar and inoculating with small amounts of culture suspensions. The following organisms were tested: gonococcus, meningococcus (one para, one regular), pneumococcus Type I, *Streptococcus hemolyticus*, *B. diphtheriae*, *B. pertussis*, *B. influenzae*. The extracts, with few exceptions, influenced favorably the growth of all the bacteria studied, and the effect varied with the amount of extract added. Kligler expresses the belief that the substances in question belong to the class of so-called vitamins.

Organ Transplantation: Thyroid.—Kawamura transplanted the thyroid through blood vessel sutures because of the favorable restoration of the circulation of the gland by this method. The experiments on dogs showed that the thyroid which was autoplastically transplanted, by means of various methods of blood vessel anastomosis, could live in good condition and functionate favorably several months after the operation, even after the interruption of the circulation for one and one-half hours. They further showed that the circulation through the transplanted blood vessels as well as glands was as good as normal, and that permanent successful results of the homoplastic transplantation of the gland are as yet not possible.

Organ Transplantation: Spleen.—There are usually two trunks of both artery and vein to the spleen from the gastro-splenic vessels. One pair enters the spleen in its lesser (left) end and another almost in the middle. In these experiments the spleen was divided in two parts, corresponding to the stream district of these large branches, after the mattress sutures had been applied transversely on it. The half of the spleen which is nourished by the larger branches was used for the transplantation. The attached omentum was cut off after ligation. The splenic artery, vein and nerves were dissected and divided. The spleen was then removed, and wrapped up in a salt sponge. After a few minutes the spleen was replaced into the abdominal cavity and its vessels were united as before, by end to end anastomosis. In one case an attempt was made to transplant the spleen into the neck. After the thyroid had been removed, the peripheral end of the splenic artery was united to the central end of the superior thyroid artery and the peripheral end of the splenic vein to the central end of the external jugular vein. In another case the spleen was transplanted into the renal vessels after nephrectomy. Most of the experiments were performed autoplastically, but in one instance the spleen from one animal

was transplanted to another. The circulation in the spleen was reestablished between one and two hours after its removal. The dissected omentum was reunited, and in a few cases the nerves also were sutured. Several days after the operation the condition of the transplanted spleen was ascertained by laparotomy. When the transplantation was successful, the other intact half of the spleen was removed and immersed in a jar filled with 10 per cent liquor formaldehyde for microscopic examination, and the animal was observed further. The results of the experiments immediately after operation were in all cases satisfactory. In spite of the interruption of the circulation from one to two hours after extirpation, the immediate circulation of blood through the transplanted spleen and blood vessels was favorable, but most of the spleen became necrotic or was entirely absorbed. The cause of this was the obstruction in the transplanted vessels, due to thrombosis. Seven autoplasmic transplantations and one homoplastic transplantation of the spleen of dogs were made. One autotransplantation was successful, the gland being normal at the end of eighty-eight days.

Influenza in Three Chicago Groups. E. O. Jordan, D. B. Reed and E. B. Fink.—p. 74.

Complement Fixation in Influenza.—The outstanding feature of the work done by Howell and Anderson on complement fixation with influenza serum is the large number of positive results with certain strains of the viridans group of streptococci isolated from cases of influenza at Camp Meade and in Chicago. The evidence indicates that such organisms probably played an important part in the morbid process even in other places.

Bacteriology of Influenza.—This report is based on a study of cases admitted to hospital with a diagnosis of influenza or pneumonia. Direct smears and cultures from 150 cases were studied by Dick and Murray. Influenza bacilli were found in eighty-seven (63.2 per cent.) of 138 cases in which specimens of sputum or nasopharyngeal secretion were obtained. In the direct smear of the sputum, the influenza bacilli were of varied morphology, appearing in most cases as minute, gram-negative bacilli with rounded ends, usually short, sometimes in pairs like a pneumococcus, but much smaller. In some smears they were so small as to be overlooked easily. In other specimens they appeared as short threads. In sputum which gave a pure culture, they were astonishingly numerous, some being within the leukocytes. Not much difficulty was found in growing the influenza bacillus in pure culture. Pneumococci of all four types were found in thirty-five (25.4 per cent.) of 138 cases in which sputum or nasopharyngeal secretion was obtained. The leukocyte count in the cases of pure influenza bacillus infection was low, corresponding to the leukopenia regarded as characteristic of epidemic influenza.

Blood and Blood Pressure in Influenza. In fifty-five cases of influenza an exhaustive daily study was made by Levinson of blood, urine and blood pressure. The blood, described usually as showing a neutrophilia in these cases, gave a lymphocytosis at certain stages of the disease, with leukocytosis and neutrophilia on recovery. The blood pressure gave a regular downward curve. Levinson is of the opinion that a diagnosis of influenza may be made from the sudden onset, headache, backache, pain in the limbs, fever, leukopenia, lymphocytosis, slow pulse, and low blood pressure.

These symptoms should be sufficient to differentiate influenza from the ordinary respiratory infections with conjunctivitis, sore throat, coryza and leukocytosis. From a study of the blood the suggestion arises that two types of pneumonia may complicate influenza; one associated with leukopenia, and hence possibly caused by the same organism that produces the original influenza, and the other with a leukocytosis and due in all probability to secondary infection by better known organisms.

Bacteriology of Influenza.—Daily examinations made by Jordan of a number of selected typical cases, mild and severe, have shown no one organism constantly demonstrable in large numbers by the methods employed. The two organisms most commonly and abundantly present in this series were the Pfeiffer bacillus and the diplococcus or streptococcus found by Mathers at Camp Meade. The Pfeiffer bacillus was found in 64 per cent. of the cases. The Mathers coccus was found about as frequently and abundantly as the Pfeiffer bacillus, although its occurrence was quite independent of that of the latter. The pneumococcus was found in about 20 per cent. of the cases. *M. catarrhalis*, the Friedländer bacillus and an unidentified gram-negative diplococcus were found at times in large numbers in the throat, nose and nasopharynx of influenza cases. Staphylococci were also sometimes present in great abundance. Two observations on suspected cases of "recurrence" or "second attack" have shown the presence in the throat of organisms (hemolytic streptococci) not found during the original attack. Both recurrences presented some of the clinical symptoms of influenza, but had a moderate leukocytosis. A third case of suspected "recurrence" likewise showed hemolytic streptococci in the throat and slight leukocytosis, but this patient had not been under observation during the primary attack. It seems probable to Jordan that an alleged "second attack" of influenza occurring within a few weeks of the original attack is at least in some cases a new infection with another organism. The observations carried out by the aerobic blood agar plate method and recorded in this paper have not shown the predominance or constant presence of any one organism in the upper respiratory tract of influenza patients. The Pfeiffer bacillus, however, has been more conspicuous than any other organism, particularly in comparison with its relative infrequency in cases of rhinitis and tonsillitis examined during the same epidemic period.

Fasciolopsis Buski Infection.—Infestation with *Fasciolopsis buski* in Goddard's opinion is to be regarded as a serious disease; and where local conditions favor it becomes of considerable importance from the standpoint of public health. The most notable symptoms are general weakness, diarrhea, anemia and edema. The rapid accumulation of fluid in the body may be accompanied by a pronounced suppression of urine without evidence of renal involvement. Contrary to certain authorities, fever is not noted, except in complicated cases. The parasite shows great variation in morphology, but with all such gradation in variation as to justify including the forms now described as *F. rathouisi* and *F. goddardi* in the species *F. buski*.

Complement Fixation Test for Syphilis.—Thomas points out that valuable modifications to the hemolytic system of

the homocomplement method are pooling serum for the determination of the hemolytic unit, the use of a light cell suspension, and finally taking as the hemolytic unit that amount of antioceptor which completes hemolysis in fifteen minutes rather than in twenty-five minutes. In the test itself, the use of pooled acetone insoluble antigens is of paramount importance, because the antigen is the key-stone reagent in this as in every other complement fixation test. The most valuable change in the technic of the test is the substitution of cold for heat fixation. This has not been the experience of some other workers, but this difference may be explained by the increased period of fixation adopted by Thomas. The use of serum with a complement content of variable quantity is theoretically not a part of an ideal system, but practically the influence of this variation is of little importance, because active serum in moderately large amounts are used. In the great majority of instances with such amounts more than enough specific antibody is present to deviate all of the complement with the routine antigen excess. Noguchi has shown that unheated syphilitic serum from an active syphilitic patient contains one antibody fixing unit to every 0.008 c.c. of serum. Therefore, 0.2 c.c. of this patient's serum would contain twelve antibody fixing units. In addition, although syphilitic serum in the majority of instances contains active complement, there are fewer specimens from syphilitic with a hypercomplementary activity than from nonsyphilitic. These two properties of specific serum reduce the possibility of error from hypercomplementosis.

Infectious Arthritis Complicating Urethritis.—Of more than 15,000 cases of urethral infection analyzed by Michel, less than one half of 1 per cent. presented joint complications. This is at great variance with the report of most authorities who report the arthritic complications to be from 2 to 10 per cent. of the urethral infections. The author ascribes these fortunate results to the early care and attention given to venereal infections. A collection of thirty cases of exostosis of the os calcis present the following etiologic factors with reference to the gonococci. Four cases of the thirty presented evidence of gonorrheal infection, and of these four cases one had a syphilitic history with a four plus Wassermann. One patient presented a tuberculous testis, but no other cause for the exostosis was discoverable. Speaking of the general treatment, Michel says that the intramuscular injections of specific vaccines, which at times gave brilliant results were on the whole disappointing in infectious arthritis of gonorrheal origin. He has discarded the intramuscular for the intravenous route in the introduction of these vaccines. While the reactions were severe (chills, vomiting, intense aches in muscles and bones), the end results were vastly better; however, there were many cases in which they could not control the acute pains without the use of opiates. Using the nonspecific proteins the results were practically specific in cases of infectious arthritis. There was not a single failure. The severe pain is controlled within three to twelve hours. The reactions are severe and the utmost care is required in the introduction of these agents. However, the results are in direct proportion to the reaction, the more severe the reaction the better the result, when the bounds of safety are not overstepped.

Legislation to Prevent Marriage of Physical and Mental Defectives, Etc.—Hutchinson emphasizes the fact that any reform and especially one which limits individual freedom must have the support of a very considerable majority of the people if it is to produce any satisfactory results. In his judgment, the proper course to adopt would be to obtain and publish statistics indicating the extent and seriousness of the evil to be combated, so as to awaken a public demand for the legislation in question. When that has been done, although there will be obstacles to surmount, there can be no doubt that at least a moderately satisfactory plan for carrying into effect the proposed legislation can be developed.

Number of Races in Species *Endameba Dysenteriae*.—Evidence is given by Smith that not all infections of *Endameba dysenteriae* remain constant from one day to another in the average size of their cysts. While the species *E. dysenteriae* can undoubtedly be divided into two races characterized by smaller and larger cysts, respectively, the existence of further races is not confirmed. Infections with *E. dysenteriae* in healthy carriers who have not been out of this country are characterized by a smaller proportion of the "small" race, and also by a reduced proportion of the larger cysts of the "ordinary" race, as compared with infections from convalescent dysenteries from abroad.

Treatment of Malaria. Intramuscular Injections of Quinin Bihydrochlorid.—The authors claim that an intramuscular injection of 15 grains of quinin bihydrochlorid in 2 cc. of water on each of two consecutive days only, causes the cessation of febrile paroxysms and effects the disappearance of trophozoites from the cutaneous blood in malignant tertian malaria. The action, however, is only temporary, a relapse occurring within three weeks, occasionally within a few days.

Id. Oral Administration of Quinin Sulphate.—Stephens and his associates found that as a palliative, 30 grains of quinin sulphate on each of two consecutive days weekly, over a period of five weeks, suffices to keep the blood free from trophozoites and to prevent relapses in the great majority of cases. It is noteworthy that the percentage of cases having crescents in the peripheral blood diminished each week, viz., from 50 per cent in the first week to 6 per cent in the fifth week of treatment.

Id. Disappearance of Crescents Under Quinin Treatment.—Under 30 or 40 grains of quinin daily, crescents do not persist in the cutaneous blood in the majority of cases for more than three weeks.

Id. Arsenic.—The authors found that the novarsendonium brand of arsenphenamin in doses of from 0.45 to 0.9 gm. is of no value in the treatment of malignant tertian malaria. A combination of arsenic with quinin is not more effective than quinin alone.

Acute Encephalomyelitis.—An abstract of this article was published in THE JOURNAL, May 17, 1919, p. 1496.

Two Outbreaks of Mild Dysentery.—Clinically the cases described by Broughton-Moore presented signs and symptoms which resembled those seen in mild cases due to the Flexner-Hiss bacillus. The more severe form of dysentery and the associated toxicity so generally found when the infective micro-organism is the Shiga bacillus were not observed in any case. The first outbreak was among troops belonging to one camp. Those in an adjoining camp remained free from infection. The troops in the camp affected had recently arrived from a distant allied country, while in the other they were British, and had been in Italy for several months. Within the period of one week twelve officers and 350 men, out of a total of 3,000 troops, fell ill with a comparatively mild form of dysentery associated with vomiting and abdominal pain. The onset was sudden and acute. In many there was collapse, and the temperature rose to around 102 F. The duration of the attack averaged three to four days, when the patient was practically able to return to his duties and the stools were normal in consistency and character. There were no deaths. The stools were numerous during the first twenty-four to forty-eight hours, and frequency persisted exceptionally to five or six days. The stools consisted mainly of mucus and bile stained watery fecal matter; some contained blood flakes or cells only, but no clots. The mucus in a few was clear and in plaques, while in others it was more opaque and occurred as fine flakes, of color and consistency varying between clear and white according as the pus and epithelial cells therein were few or numerous. It appears that these outbreaks were due to an intestinal intoxication dependent on the proliferation and mild toxicity of the Schmitz bacillus.

Traumatic Rupture of Heart Without Fracture or External Lesions.—While engaged in fire practice in the regimental lines a soldier was pulling the wheeled fire pump when, coming downhill, it ran away with him, and he was crushed between a stone wall and the cross-bar handle of the pulling shaft, which apparently caught him across the middle of the chest. He was seen to fall dead at once. Externally there was some congestion of the right eye, and a small cut and contusion on the right side of the forehead. No other contusions or lesions were found anywhere and no fractures or hemorrhages, though the saliva was tinged with blood, possibly from some undiscovered cut in the mouth. The base of the skull was not fractured; there was marked pachymeningitis along the superior longitudinal sinus. The abdomen was normal; the ribs were unfractured, but were very pliable, so that the chest could be compressed easily. The lungs were normal. The pericardium was full of blood but undamaged. The heart was very small, being only about 3½ inches long and 3 inches broad. The valves and heart muscle were apparently normal, and there was no trace of aneurysm or old disease. In the wall of the right auricle, between the right coronary artery and the entry of the inferior vena cava, was a small rent measuring about three-fourths by one-half inches. Bilderbeck suggests as cause of this curious accident that at the moment of impact the man may have taken a deep inspiration, engorging the right auricle, which then burst on sudden compression through the costal wall by the cross bar of the shaft of the fire pump.

Brachial "Neuritis" and Treatment. Attention is directed by Williamson to the etiology of the affection, and especially

to pressure on the nerve trunks of the brachial plexus in the posterior triangle of the neck as one exciting cause; and to the value of supporting the arm in a suitably arranged sling. He cites cases to show how various kinds of pressure on the nerve roots such as from the suspenders, a shoulder strap, a fall, a blow, carrying a heavy weight on the shoulder, etc., may cause this trouble. He has treated these cases of brachial neuritis by placing the affected arm in a sling. The sling should pass over the shoulder of the normal arm, and it should be so arranged that it passes under the elbow of the affected arm and slightly raises it. The shoulder and the clavicle are thus slightly raised, and pressure on the nerve roots at the lower part of the posterior triangle of the neck (near the first rib) is prevented; also the weight of the arm is supported and dragging on these nerve trunks prevented. All tight braces or shoulder straps should be removed at once. The arm should not be allowed to hang by the side. Most of Williamson's patients, but not all, recovered promptly or improved markedly by the use of the sling, with a pyrazolon derivative given internally.

Febrile Urticaria.—The symptoms in the two cases cited by Lawrence were practically identical, and were characterized by five days' pyrexia, by a diffuse eruption partly resembling urticaria and partly angioneurotic edema, and by intolerable itch. They both occurred in the same hospital within a week of each other. None of the known causes of urticaria were present, and the questions arise whether it was not more than coincidence that these two uncommon cases appeared so close together in time and place, and whether there might not be some unknown specific infective agent to account for them both.

Antimony Tartrate in Kala-Azar.—In the case cited by Low antimony tartrate evidently acted as a specific against *Leishmania donovani*, and sterilized the patient of his infection. Low cautions, however, that antimony in large doses, given over prolonged periods of time, produces fatty changes in the liver and kidneys, which may seriously damage the resisting powers of the patient, and may even cause death. Therefore, antimony should not be given for longer periods than necessary, and it is important that some definite test should be evolved which will indicate when the infection of kala-azar has disappeared and the patient is cured. If antimony is finally proved to destroy the *Schistosoma hematobium*, then a similar test to determine when this destruction has taken place is required. In all cases where antimony tartrate is given intravenously the patient should be confined to bed on the day of the injection and kept there till the day after, and should be watched carefully throughout the course, any indications of gastric or constitutional disturbances at once contraindicating further injections. Not more than two injections a week should be given, and the salt should not be given in too concentrated a form.

Japan Medical World, Tokyo

"Biologic Nature of Virus of Typhus Fever and Prophylactic and Therapeutic Study of Reconvalescent Serum." S. Kusama.

June 1, 1919

"Treatment of Malignant Tumor with Emulsion of Autogenous Tumor Tissue." K. Ohta.

Biologic Nature of Virus of Typhus Fever. Kusama is convinced that the virus of typhus is present in the platelets. The Japanese monkey was infected with the virus and the blood was withdrawn in from 5 to 63 days from the subsidence of the fever and the serum was prepared. With this serum, Kusama tried both prophylactic and therapeutic experiments. Two monkeys were injected hypodermically with 20 gm. of the serum per kilogram body weight, and on the next day, the virus was injected into the vein. No symptoms developed. These two monkeys were given the virus after some score of days and the typical symptoms developed in them, thus proving that they had not any a priori immunity against the disease, but that they were protected from the infection by the prophylactic power of the reconvalescent serum that had been given them. Monkeys were infected with the disease and the reconvalescent monkey's serum was

administered hypodermically in doses of 0.5 to 0.6 gm. in doses of from 0.5 to 2.0 gm. per 100 gm. of body weight. Each time a remarkable improvement in the course of the shortening of the duration of the symptoms was effected. The latter seems yet to be proved by further experiments.

Treatment of Malignant Tumor with Emulsion of Autogenous Tumor Tissue.—Ohta cites the case of a woman, aged 30 years, who had a typical medullary carcinoma of the breast. For two months she was injected with a saline emulsion of her tumor cells. The result was an improvement in the local and general symptoms; microscopic evidence of a change in the tumor cells, the tissue taking on the appearance of chronic inflammatory tissue. There was no evidence of further growth of the tumor. The patient died of pulmonary tuberculosis. At the necropsy carcinoma metastases were found in the liver.

"Case of Teratoma of Testiculo Rube, Throwing Light on Origin of Peptic Ulcer." J. Taylor—p. 1027.

Antimony Tartrate for Bilharziasis. Christopherson claims that the intravenous injection of antimony tartrate not only kills first the parasite (*Schistosoma hematobium*) in situ but later it kills the embryos in the ova deposited in the terminal vessels, and sterilizes the ova so deposited, and that the patient is cured not only of his bilharzia parasites but that he ceases to be a bilharzia carrier and cannot propagate the disease.

Atypical Strain of *B. Paratyphosus*.—The atypical characters found in a micro-organism temporarily classified as a strain of *B. paratyphosus* B isolated by Broughton-Acland and his associate, Lagane, from the blood of an enteric patient, who showed characteristic clinical symptoms of such an infection, appear to be an example of the marked variation that exists among strains within a group of micro-organisms.

Medullary Symptom Complex. The following is a summary of the symptoms in the case cited by Owen and Leighton. A woman, aged 47, stated that left sided occipital headache was the only premonitory symptom. Acute onset, without loss of consciousness or convulsion, but with vomiting (once), persistent uncontrollable hiccup, tremor (left ear), and intense giddiness; forced movements toward left, left sided cerebellar hypotonia and ataxia (slight), with nystagmus on looking to left; inability to swallow, with paralysis of left vocal cord, dysarthria and paralysis of palate; left pseudoptosis, enophthalmos and small pupil; paresis of left sternomastoid and trapezius; anesthesia and the two-anesthesia of right side of body and face, and left face. Tactile sensibility, joint sense, vibration sense, all normal. Hypertrophied heart, high systolic and diastolic blood pressure, no albuminuria; Wassermann reaction negative. A tentative diagnosis of a lesion of the left posterior inferior cerebellar artery, was made. A second more detailed examination confirmed this diagnosis.

Perforating Wound of Heart. Polson's patient was stabbed in the neck and back and four times in the thorax. Perforation of the thorax was produced on each side. Three of the four thoracic

wounds were over the heart; one of these produced pneumothorax, opened the pericardium, and penetrated the left ventricle, which was sutured about two hours later. Nevertheless the patient survived for five days, then dying from septic infection of the pleurae and pericardium.

Teratoma of Testicular Relic.—Taylor cites the case of a man who complained of irregular attacks of severe pain in the epigastrium of two years' duration and recently becoming worse. This pain, which shot through to the back, did not seem to have any definite relation to the taking of food; it frequently came on in the night. It was accompanied by nausea but no vomiting. The bowels were constipated; no melaena. The patient had lost in weight. Laparotomy was performed and a large ulcer found on the lesser curvature close to the cardiac orifice, but actual organic constriction was not present. The duodenum was much dilated; it was somewhat congested; no evidence of ulceration. Behind the peritoneum at the duodenojejunal junction, and partly obstructing it, was a rounded cystic swelling about the size of a duck's egg. It was closely applied to the front of the aorta and had a communicated pulsation from it. This obstructing tumor was carefully separated from the aorta and removed and the ulcer excised. The tumor was a teratoma of a testicular relic. Taylor thinks that the case demonstrates very clearly the fact that obstruction at the duodenojejunal junction, which, according to the theory advanced by Lane, is usually produced by chronic intestinal stasis, and which was brought about here by the pressure of a tumor, may be directly responsible for the development of peptic ulceration.

Medical Journal of South Africa, Johannesburg

March, 1919, 14, No. 8

Maternal and Antenatal Pathology. A. S. Wells.—p. 388.

*Effort Syndrome. G. D. Maynard.—p. 395.

*Use of Salt Water in Preventing Influenza. W. Watkins-Pitchford.—p. 398.

South African Cercariae. F. G. Cawston.—p. 401.

Effort Syndrome.—Maynard prefers this appellation to the terms, soldier's heart, the irritable heart of the soldier, disordered action of the heart or D. A. H., and neurocirculatory asthenia. He analyzes 121 cases. The characteristic symptoms of this condition are those common to myocardial weakness from many causes. The frequency with which Maynard found them in his cases is as follows: dyspnea, 92 per cent.; palpitation, 80 per cent.; precordial pain, 54 per cent.; weakness, 86 per cent. The average systolic pressure was 129 mm., the diastolic, 74, and pulse pressure, 55. Some apparently definite dilatation of the heart was noted in 46 per cent. of the cases. Systolic murmurs were observed in the following order of frequency: tricuspid, 35 per cent.; mitral, 30 per cent.; pulmonary, 9 per cent., and aortic, 6 per cent. The sinus arrhythmia were observed in 50 per cent. of the cases. Extra systoles were noted in 15 per cent.

Use of Salt Water in Preventing Influenza.—In the early days of the recent epidemic of influenza in Cape Town, the public were advised, through the medium of the daily press, of the possible preventive value of systematically douching the nasal cavities and gargling with warm salt water. In order to ascertain, if possible, the experiences of those who had employed salt water in the manner recommended, the South African Institute for Medical Research appealed, through the medium of the public press of the Cape Province, for personal reports from all those who had adopted this measure. Reports concerning 786 individuals were received, and the information thus provided enables us to arrive at, at least, a tentative conclusion as to the influence of this procedure on the development and course of the disease. The general conclusion which Watkins-Pitchford says all the facts appear to warrant is that the frequent and regular douching of the nasal and nasopharyngeal cavities with salt water was definitely beneficial. The evidence shows that the procedure, when systematically carried out, was capable of diminishing the probability of such judgment (of the onset of influenza) becoming permanent, or of modifying at least the dose of poison so received.

Necessity for Organizing a System of School Nurses. L. Guinon.—p. 299.

*Measurements of Children. A. Bleyer.—p. 311.

Infantile Scurvy.—Comby states that the sexes were equally divided in his sixty cases of scurvy in infants, but none of the children was less than 6 months old; one was over 3, two were 8 years old, and one 9. The previous instalment of his article was reviewed in these columns, page 1875. He reiterates in conclusion that orange juice should be given systematically as a preventive to all children being fed sterilized milk.

Measurements of Children.—Bleyer compares the figures as to height and weight in 2,000 schoolchildren at Vienne, a manufacturing town in France, with similar data from Paris and from the United States. The weight of both boys and girls was higher at Vienne than at Paris and in the United States, except that the United States figures for the ages 12 to 14 were a little the highest. The same superiority of the Vienne children was also apparent in the weight, surpassing the weight of the Paris and United States children except that boys of 13 and 14 and girls from 12 to 14 weighed a little more in the United States figures. Bleyer's research was done under the auspices of the American Red Cross Children's Bureau.

*Foreign Treatment of Influenza. M. Renaud.—p. 720.

*The Finger Prints of the Blindfold. Ferrier.—p. 723.

*Doses in Roentgen Work. H. Guilleminot.—p. 726.

Etiology of Cancer.—Robin presents what he says is a new conception of the origin of cancer. It is based on his noticing that cancer tissues and the tissues around the focus contain much more water than other tissues. They share this tendency to hydration with all very rapidly growing tissues, only that they have it in an exceptional degree. The cancer tissue has less total residue than normal tissue. The reverse is observed in tuberculous lung lesions, the content in organic and inorganic matters being much above normal especially in the region around the focus. He regards this as an aid in the defense, nothing of the kind being observed with cancer. He gives further figures in detail from a number of cases of cancer of the liver, pancreas, etc., and from healthy corresponding organs, "all testifying to a double or almost triple proteolytic ferment action in the tissues around the cancer, not in the cancer itself. The dissociating action of this proteolytic ferment may by some reverse action incorporate some of the dissociated amino-acids in some of the cells of the organ, thus imprinting on these cells a tendency to rapid growth and anarchistic multiplication, the rapidity of their growth not leaving them time for differentiated evolution. Contrary to the way the tubercle grows, the cancer builds itself up out of the products of dissociation of the proteic substances of the organ on which it is developing, selecting preferentially those among the amino-acids which Osborne and Mendel regard as the growth elements (hexonic bases)."

Traumatic Shock. Quémé refers to the traumatic toxemia with its set of symptoms indicating depression of the vital processes while the mind is not impaired. He devotes 2 pages to analysis of the literature on the subject published by the Allies, thus compiling for future investigators the data on the subject accumulated during the war. The number of clinical observations published was comparatively small, but they brought about the revolution in the concepts and treatment of shock. In the surgical posts at the front traumatic shock sometimes was responsible for the death of more than half of those that could not be moved. However, that when for special reasons it is impossible to remove the focus, instead of mere expectancy, we might temporarily fasten the toxins in situ, as Hertz Boyer did in one of the intense traumatic shock filling the hatred of the third

wounds with a solution of formaldehyd and methylene blue and giving copious hypochlorite irrigation.

Loose Bodies in Joints.—Coudray gives the details of six personal cases and reviews those published by others. The distinction between a traumatic loose body and one that is due to arthritis without effusion has seldom been made with precision. The arthritis may be explained by rheumatism, by a trauma, or by some nervous affection. The loose bodies cast off by a subchondral tuberculous osteitis seem to occur more frequently than is generally recognized. They have sometimes been mistaken for traumatic bodies. There is no evidence of the existence of a dissecting osteochondritis. Coudray's article is a sequel to one on the same subject published in 1905 reporting considerable experimental research in this line on dogs. Time and experience have only corroborated his earlier statements.

Avril, 1919, 14, No. 4

*Breech Presentation, S. Remy.—p. 125.

*Decapsulation of Kidney in Puerperal Eclampsia, Jullien.—p. 131.

*Roentgen Treatment of Uterine Fibroma, R. Karhausen.—p. 136.

Breech Presentation.—Remy reviews his experience with 24 cases of breech presentation. It shows that when the uterus is contracting energetically the pelvis and the trunk of the child are delivered easily and rapidly, bringing down the arms and delivering the head by the classical means. Cases of this kind cannot be classed as fetal dystocia. But unfortunately this smooth delivery does not invariably occur. In his 24 cases intervention was required in 11, including 4 in the group of 17 in which pelvic presentation was discovered early. In the other cases Remy was summoned on account of serious dystocia from breech presentation. Intervention was usually required in the first group because the expulsive forces were too weak. Two died of the 9 children in the cases of intervention and 2 other fetuses were dead when the case was first seen. The mothers were primiparas in the two cases that proved fatal for the children, and in both the arrest was at the pelvic inlet. In such cases, if the Pinard-Mantel procedure does not prove successful, he would apply Olivier's porte-lacs to pass a fillet around the neck of the fetus. He thinks this would have succeeded in one of these cases if the whalebone had not broken just at the critical moment. The child was successfully extracted but it died during the intervention. In his 9 cases of breech presentation ending in normal delivery, 7 of the women were primiparas but the normally vigorous labor contractions insured comparatively easy delivery. Intervention was required in 3 cases as the labor contractions were too weak with arrest at pelvic floor, but delivery by classic methods proceeded smoothly in 2 cases, one a primipara. The other fetus had died before the intervention.

Decapsulation of the Kidney in Puerperal Eclampsia.—Jullien reports the case of a woman of 25 in eclampsia which had persisted after delivery, the woman still in profound coma with almost complete anuria. The pregnancy was at seven and a half months and the fetus had been spontaneously delivered. In eighteen hours thereafter she had voided only 130 cc. of urine, and it contained 12 gm. of albumin. Decapsulation of both kidneys was then done and the coma gradually passed off and the woman recovered. Jullien warns that this success must not mislead us to demand more of decapsulation than it is capable of yielding. It has no appreciable action on changes in the liver or brain, but it is the sovereign remedy for derangement of the secretion of urine. Statistics show that the secretion of urine is reestablished in fully 80 per cent. of the cases, although the mortality in eclampsia, notwithstanding surgical treatment, is 39.66 per cent. Of course the operative cases are only those of exception gravity. Tisserand has recently pointed out that while decapsulation starts the secretion of urine anew in cases of mercuric chlorid poisoning, yet the patients die just the same. Decapsulation should be considered in eclampsia only in the cases with anuria. He performed the simple bilateral operation without special assistance, under brief ether anesthesia, the whole complete in less than twenty minutes.

Roentgen Treatment of Uterine Fibroma.—Karhausen emphasizes the fine result obtained in this case. The patient was a woman seven years past the menopause. There had been disturbances from the fibroma for fifteen years, but no permanent benefit had been obtained from prolonged medical measures. Eight exposures of the tumor were given at three to six weeks' interval and the fibroma, which had reached to 9 cm. above the pubis, gradually subsided, but adhesions were painful and subhysterectomy was finally done.

*Chronic and Duodenal Ulcer, E. Kummer; Id. E. Bircher.—p. 673.

Psychoanalysis for Children.—Frank illustrates by a number of concrete examples the imperative necessity for seeking out the cause when children change to be irritable and display anger and hatred for the ones they really love best. Psychoanalysis may give the clue, and change of scene to a sympathetic environment may ward off irreparable injury, and save the child from a criminal career. The question is, where can such children be sent where they will get the patience and affection they require, in wholesome surroundings, with other children? A temporary change from the paternal roof is so indispensable that Frank declines to take any such case unless this is arranged. In conclusion he emphasizes the internal conflicts to which illegitimate children are so often exposed. The more intelligent the child, the more keenly he feels his ostracism and resents the prejudices of society. It is not a casual coincidence that so many professional criminals are of illegitimate birth. Frank says further that the psychobiologic phase of the subject of the declining birth rate never gets mentioned in scientific discussions. Even physicians are not qualified to discuss it as their university training leaves out of account altogether the important normal and pathologic psychic manifestations of the reproductive functions. And yet, he asks, "Are not these psychic processes the axis on which our entire human life revolves, its happiness and its unhappiness? Are these forces actually imponderables for the physician? A correct understanding of human biology leads inevitably to the conclusion that man can live a healthy and happy life only when he is not fighting like a Don Quixote against the forces working in him, the gregarious instinct and the longing to love and be loved. . . ." "The university courses in medicine, law, theology and pedagogy, although the professions they teach have to deal always with man and his relations with his environment, yet pass over entirely the normal or pathologic life of sentiment and sex relations in general."

Mosquitoes in Switzerland.—Galli-Valerio was delegated by the Public Health Service to collect data on this subject. He found anophelines up to altitudes of 1,143 meters and the culex to 2,300 meters (over 7,170 feet). He noticed an unusually long larval stage in some of the mosquitoes, especially the nigripes; some of the larvae of the latter were 6 to 8 months old before they changed to the pupal stage. He found mosquitoes in every canton, and describes their biology. One town had no standing water and hence no mosquitoes except in the cisterns for fighting fires.

Chronic Gastric and Duodenal Ulcers.—Kummer discusses the pathology and the statistics while Bircher discusses the operative technic. These two comprehensive articles formed the leading addresses at the fifth Swiss Surgical Congress. According to Kummer's statistics, gastro-enterostomy offers two or three times less vital danger than resection and exci-

sion, while the functional results are equally as good, irrespective of the site of the ulcer. Nothing is more difficult, he says, than to cure a peptic ulcer, and this should be borne in mind before doing any operation of the kind. Cancer developed after gastro-enterostomy in 2 per cent. between 1890 and 1910, but only in 0.13 per cent. in 1910 to 1917, in a total of 1,152 operations of the kind by twenty-three Swiss surgeons, including 252 duodenal ulcer cases.

Bircher deplures that gastro-enterostomy has not answered all anticipations, and he ascribes this to the neurotic factors involved in the ulcer. The ulcer seems to be the outcome of a vagotonic vicious circle formed by hypersecretion, retarded evacuation and pylorospasm. The gastro-enterostomy breaks up this circle as thyroidectomy breaks up the vicious circle in exophthalmic goiter. The pylorospasm is arrested; this improves evacuation conditions, and the pains may disappear completely at once. The question is whether it may not be possible to arrest the pylorospasm in some simpler way, possibly by severing the vagus or the contracting muscle. He reiterates that at present resection of a transverse segment of the stomach is superior to gastro-enterostomy in every respect, and it takes no more time than the latter. He declares that this technic should be applied without exception for ulcers that are not near the pylorus, also for all hard, boring ulcers, as well as with the slightest suspicion of cancer. Excision of the ulcer alone deforms the stomach and may compel another operation later. He declares that a bleeding ulcer should not be operated on. The best way to prevent dangerous hemorrhage is by early resection. Albert Kocher said in the discussion which followed that gastro-enterostomy is still as ever the preferable operation for gastric and duodenal ulcer. He emphasized the rarity of malignant degeneration, saying that the wide divergence in the figures of different surgeons, from 0.5 to 70 per cent. is undoubtedly due to errors in interpretation. He related that he had personally examined the Mayos' specimens, and was convinced that much of what they labeled cancerous degeneration of ulcers was in reality merely atypical proliferation of epithelium. Regenerative processes in the gastric glands assume most peculiar shapes, and we have no means to date to differentiate them except by the outcome.

De Quervain made a plea for refraining from gastro-enterostomy if the expected ulcer is not found. Peptic ulceration occurs oftener than is generally recognized. It may escape detection or the patient may apply to another surgeon and the first never hear of the peptic ulcer. Even if he does learn of the symptoms, he is very apt to ascribe them to the primary ulcer. De Quervain found in three cases a scrap of silk thread in the depths of the peptic ulcer, and since then has used exclusively a special, very slowly absorbed catgut. Other material is used only for closing the slit in the transverse mesocolon, taking the button sutures 1 cm. apart, through stomach, mesocolon and jejunum. Kopp reported a case of recurring hematemesis and melena in which the symptoms pointed solely to the stomach or duodenum except for two weeks or jaundice, but necropsy in less than three months revealed a round ulcer in the gall-bladder and one in the cystic duct.

*Symptomatology of Epidemic Meningitis. L. Nelli—p. 307.

April 27, 1919, 40, No. 34

Therapeutic Pneumothorax for War Wounds of Chest. G. Pisano.—p. 317.

Symptomatology of Epidemic Meningitis. Nelli states that in his 100 cases of epidemic meningitis, headache, vomiting and herpes were observed in every case and the pulse was always very slow, down to 35 and 40 in some cases. As the prognosis grew graver the pulse became accelerated. There were manifestations in the skin only in about 10 per cent. of the cases. In one patient there was actual purpura with swelling of the joints. In two cases that terminated fatally the course was apyretic throughout, and in all the fever was seldom above 38 or 38.5 C.

*Influence of Mercurial Treatment on the Coaguloreaction. S. Scigliano.—p. 374.

*Roseola Simulating Syphilis. L. Martignetti—p. 377.

*Fracture of Petrous Bone. F. Niccoli.—p. 380.

Influence of Mercurial Treatment on the Coaguloreaction.—Scigliano refers to the coaguloreaction of Hirschfeld and Klinger, proposed as a serodiagnostic test for syphilis. It was applied by him systematically in a large number of cases parallel with the Wassermann test, applied by the original and by several modifications of the original technic, repeating the tests at a year's interval while 45 patients were being given vigorous treatment. The results show that mercury does not affect the findings of the coaguloreaction as it affects the Wassermann reaction. That is, recent mercurial treatment does not modify the serum of syphilitics so as to deprive it of the properties which induce the coaguloreaction. This reaction is less sensitive to mercury than the Wassermann, and consequently may prove decisive in dubious cases.

Roseola Simulating Syphilis.—Martignetti reports six cases in which the skin presented roseolar, apparently typical syphilids, but there was nothing at the time or later to suggest this disease. He explains them as probably due to autointoxication or some infection, possibly influenza.

Fracture of the Petrous Bone.—Niccoli comments on the difficulty of diagnosing fracture of the petrous bone as the symptoms may suggest constitutional disease, coma from diabetes, sunstroke, uricemia or cerebral hemorrhage. Treatment usually has to be expectant, combating shock, intracranial hemorrhage, infection, hypertension and compression, unless surgical measures are indicated from the first.

Rivista Critica di Clinica Medica, Florence

May 3, 1919, 20, No. 18

*Effusion with Induced Pneumothorax. G. Breccia—p. 205. Continued in No. 16, p. 151.

Effusion with Induced Pneumothorax.—Breccia ascribes to the compression on the vessels in the hilum of the lung the disturbance in the circulation which is the main cause of the pleural effusion with therapeutic pneumothorax for pulmonary tuberculosis. This is also the cause for the effusion with heart disease, the enlarged heart pressing on the hilum and compressing its vessels. This explanation is a guide to treatment, as the presence of fluid in the pleura may push down the diaphragm or displace the mediastinum, and thus mislead one as to the absolute pressure in the pleura in inducing the pneumothorax. The effusion is liable to be rapidly resorbed, modifying completely pressure conditions with the pneumothorax, unless measures are taken at once to maintain the curative pressure on the lungs which abates as the fluid is absorbed. If the effusion shows a tendency to remain stable, he advises to respect it, as also when the effusion displays a progressive tendency, unless it becomes excessive, when it requires treatment as for any pleural effusion. He emphasizes that the pleural effusion alone may exert the desired pressure on the lung, and in connection with the pneumothorax may regulate automatically the induced pneumothorax. He discusses further the indications when the effusion is purulent, mentioning parenthetically that the 12,000 soldiers passing through his service in the last two years amply demonstrated that the lung is able to expand and recuperate function almost always after a war wound of the chest affecting a sound lung. In the tuberculous lung,

however, conditions are different, and time alone will show what share the pleuritic changes have in the final outcome of recovery under induced pneumothorax.

Rational Diets.—J. G. Ochoa—p. 193. *Cont'n.*

Operative Cure of Plastic Limitis.—L. Urrutia—p. 201.

Tabetic Crises.—J. Vilató—p. 207.

Electric Treatment of Hyperchlorhydria.—C. M. Colmenarejo—p. 217.

Rational Diets.—This is the seventh in a course of popular scientific lectures on this subject.

Chronic Inflammation of the Cellular Tissue of the Stomach.—Urrutia gives a number of illustrations of the case of Brinton's plastic limitis in which he resected all but a long narrow horizontal segment, including the cardia. This was sutured to the side of the jejunum. Urrutia discusses the nature of this "leather bottle stomach," inclining to accept a malignant origin. In this case the man was restored to apparent clinical health for over half a year but then abdominal pain and cachexia developed and death ensued eight months after the operation, twenty months after the first vomiting and loss of weight had attracted attention.

Tabetic Crises.—Vilató reiterates that tabetic crises in stomach, intestine, pharynx or esophagus may be the first manifestation of tabes, and hence the practitioner should be on the alert to suspect it in every possible manifestation of the kind. To aid in this he describes in minute detail the forms which these crises may assume.

Electric Treatment of Hyperchlorhydria and Gastric Ulcer.—Colmenarejo applies the continuous current in treatment of these conditions, keeping up the daily sittings for about two months. He begins with 5 ma., gradually increasing to 30 ma. by the end of the month. The left-protected positive electrode of about 15 square cm. is placed on the epigastrium, the negative in the dorsolumbar region. The second month he supplements this with brief exposures to a weak faradic current to combat the atony and dilatation. If there has been much hemorrhage from the ulcer, he waits for two or four weeks before beginning the electric treatment. The results have been most gratifying in nearly all his cases.

Blunder in Sex Determination.—D. Casadevall—p. 73.

Chronic Nephritis in Boy of Eleven.—P. P. de F. G. —p. 77.

Pulmonary Tuberculosis in Children.—Borobio—p. 85.

Pseudohermaphrodite.—Casadevall reports the case of a girl 2 years old, brought to the clinic on account of inguinal hernia, and the "hernia" proved to be testicles. The amazed parents left the clinic with a son instead of a daughter. The case reaffirms the importance of being wary in classifying the sex when there is the slightest anomaly in the genital organs. The labia were somewhat overdeveloped in this case, and on one side the skin was somewhat ornamented and shrunk by cremaster retraction. The supposed vagina was the outlet merely of the bladder. Several illustrations of the case are given.

Child Welfare Work.—J. A. B. —p. 97.

Parasitic Air Cysts in Lung.—A. Mola—p. 101.

Chronic Hemiplegia.—J. Bonabá—p. 110.

Tumor of Pineal Gland.—J. Morquio—p. 119.

Acute Rubeola.—P. P. de F. G. —p. 127.

Meningeal Reaction in Mumps.—J. Bonabá—p. 130.

Echinococcus Cysts in Lungs.—A. Zerbino—p. 137.

Child Welfare Work at Montevideo.—Bauzá describes the work aims of the child welfare stations, and insists that the work should include training in the care of children, prenatal consulting station, well baby station and a children's clinic for children of all ages.

Case of Chronic Purpura.—Bonabá relates that the child of 6 subject to recurring eczemas for four or five years had

developed in the last few months a purpuric eruption with vomiting of blood and bleeding from the gums until the anemia was intense. The reds numbered only 950,000; the hemoglobin only 15 per cent. As a last resource to arrest the recurring epistaxis, the nasopharynx was cauterized. It accomplished this, and the hemorrhagic tendency seemed to subside, the blood regenerated and the present condition has been very satisfactory during the nine months since. He is convinced that the cauterization was responsible for this, as all other known measures had proved ineffectual, and the child was dying from the repeated losses of blood, especially the recurring epistaxis.

Tumor of Pineal Gland.—Morquio's patient was a boy of 12, previously healthy until he began to complain of headache and the clinical picture of tuberculous meningitis became installed, quite typical, except that the spinal fluid seemed to be normal. The child died at the end of a month, and necropsy revealed sarcomatous changes in a tumor in the pineal gland, probably of congenital origin.

Meningeal Reaction in Mumps.—Bonabá emphasizes the danger of mistaking the meningeal reaction in the course of mumps for actual meningitis, especially in cases in which the mumps was abortive or so mild that it was overlooked. The meningeal reaction is generally mild and transient, but Morquio has reported a case of total permanent deafness as a sequela, and others have published cases of encephalitis, optic neuritis, zona or polynenitis following mumps. The meningeal syndrome may persist for some time, up to two months in Massary's case. Lymphocytosis is the rule in these cases, but it is not invariably present. Repeated lumbar puncture showed no trace of it in three children with typical mumps. Massary found it constant in examining 635 soldiers with mumps; it was equally pronounced in those without any definite meningeal reaction. But the lumbar puncture may have to be repeated several times before it becomes evident. Massary calls it the lymphocytic meningitis; bradycardia and white demography are common.

Echinococcus Cysts in Lungs.—Zerbino reports two cases of hydatid disease of the lung in which the hydatidiform cyst in the lung ruptured spontaneously and the contents were coughed up by the children. The cure was soon complete in both cases as is the rule in children with small and young cysts, the contents of which are often sterile. If the membrane has been expelled, treatment should be only symptomatic. The position of the cyst does not affect the outcome as the contents are expelled by coughing.

Leprosy in Northern Brazil.—J. A. Astar—p. 187.

Bifurcated Claw Thumb.—A. F. de Magalhães—p. 189.

Leprosy in Northern Brazil.—Astar relates that a leper asylum was founded in 1816 in the state of Pará, the disease having probably been imported from Europe. In 1900 there were twenty-five admissions and in 1917, 112, the authorities having recently made declaration of the disease compulsory. Of the total 882 new cases since 1894, 600 were males. Only 4.50 per cent. were under 10 years of age; 27.21 per cent. were between 10 and 20; 20.29 per cent. 20 to 30; 21.54 per cent. 30 to 40; 12.47 per cent. 40 to 50; and from 5 to 0.22 per cent. in a declining scale in the following decades of life. Astar does not know of any other statistics classified by ages. He says that the new cases now in Pará are nearly all in subjects under 20, and argues that the immunity of the older adults is probably due to an auto-vaccination from repeated small inoculations of the virus. This assumption would explain the relatively small percentage of children that develop leprosy in a leper's family. He mentions further that the distribution of leprosy in Pará does not coincide with that of malaria. In the Gurupa malarial zone there has been scarcely one new case of leprosy in the last twenty years, and he queries whether this may not be the direct consequence of the ravages of the malaria among the children. Leprosy has been growing less frequent at Pará since malaria has been making greater headway there.

*Resection of Ileocecal Segment for Cancer. S. Córdoba.—p. 49.
Cancers of Large Intestine. J. C. R. Morales.—p. 54.

Cancer of Ileocecal Segment.—Córdoba states that the clinical recovery has been perfect in the case described, the man of 45 six months later having gained much in weight and regained almost the whole of his strength. The case is illustrated. Córdoba believes that it is the first operation of the kind followed by entero-anastomosis on record in Venezuela.

Progresos de la Clinica, Madrid

March, 1919, 7, No. 75

- *Reconstruction of the Face. A. Cortés Lladó.—p. 97.
*Extraction of Cataract in the Capsule. F. P. del Fresno.—p. 117.
*Postinfluenzal Thyroid Insufficiency. W. L. Albo.—p. 122.
*Ossification from the Periosteum. A. H. Carmona.—p. 129.
Spanish Mineral Waters in Treatment of Disease of Digestive Apparatus. B. R. Campos.—p. 135.

Reconstruction of the Face.—Lladó's second article on this subject is also profusely illustrated, discussing how to avoid disfiguring scars from the suture, and prevent associated movement resulting from anastomosis of muscles or nerves. In one of Chutro's cases the deformity of the mouth had been corrected perfectly but, as the man laughed, the shoulder on the other side was lifted up. Lladó has been making a special study of plastic facial surgery in France and compares the methods of different surgeons and the indications for the different types of interventions.

Cataract Operations.—Del Fresno describes with two colored plates his modification of von Graefe's operation for extraction of cataract in the capsule. The loss of vitreous humor is much less, he says, when a movement of extraction is combined with pressure, as he explains.

Postinfluenzal Thyroid Insufficiency.—Albo gives the details of two cases in which, following an attack of influenza, girls of 11 and 10 developed somnolency and headache, and became forgetful. These were the only cases of unmistakable hypothyroidism he encountered although he had many cases of postinfluenzal nervous and mental disturbances, neuritis, meningitis and meningeal reactions, chorea, mild or paralytic, and psychoses. In one of the hypothyroidism cases, under thyroid treatment the somnolency improved at once, the headache disappeared by the third day and the memory returned to normal the fourth or fifth day. In the second case the headache yielded to the thyroid treatment but the somnolency and the impairment of the memory persisted for over three weeks when last seen; the ultimate outcome is not known. In conclusion Albo remarks that influenza may sometimes have the opposite effect, exaggerating the functioning of the thyroid and entailing symptoms of exophthalmic goiter, especially in persons with simple goiter or otherwise predisposed.

Periosteum Implants.—Carmona has continued his experiments with auto-implants of periosteum in dogs, and reports that microscopic sections later confirmed the positive results. The auto-implants of bone alone showed no signs of ossification. It is evident that bone deprived of its periosteum cannot be expected to regenerate, while the periosteum alone can be depended on for this unless the tissues are too old.

March, 1919, 1, No. 3

- *Missed Abortion. S. García Marruz.—p. 137.

Missed Abortion.—Marruz explains the case he reports saying that the fetus had committed suicide in a loop of its own umbilical cord. The uterus, after an ineffectual attempt to expel it, continued to tolerate the dead fetus. The size of the uterus persisted the same for three months, and investigation then revealed the entire ovum of about ten weeks' development loose in the vagina. He warns of the extreme discretion which circumstances may require in these cases of missed or delayed abortion, citing the Playfair case in which a verdict of \$50,000 was rendered against the physi-

cian who mistook an old case of abortion for a complete one, the recent process and told his wife of it.

- *Treatment of Urethrovaginal Fistula. J. C. Pineda.—p. 211.
Transfusion of Blood. G. E. Aróstegui.—p. 213.

Urethrovaginal Fistula.—Pineda reports the successful cure of a case with considerable destruction of the urethra. He reconstructed it out of a flap from the vagina, using the Duboue and the Ferguson-Braquehay technique. He kept the retention catheter in place for twelve days.

Revista de Medicina y Cirugía Prácticas, Madrid

March 14, 1919, 122, No. 1546

- *The Celiac Plexus Reflex. M. Bañuelos.—p. 289.

The Celiac Plexus Reflex.—Bañuelos has continued his research on what he calls the celiacocardiac reflex, and now states that pressure on the celiac plexus not only modifies the rhythm of the heart beat but influences the arterial pressure. The respiration rate and the pupils also feel the influence of this stimulation and likewise the tone of the peripheral vessels. The respiration is increased by five or ten inspirations per minute and the pupils dilate. The latter occurs more strikingly in persons of the sympathetic-tony type; with vagotomy there is no appreciable dilatation. There is also a tendency to vasoconstriction of the capillaries in the face. Experiments on three dogs with the carotid or femoral artery exposed for the purpose confirmed the clinical findings. The diagnostic significance of this reflex is most marked in the abnormal response to the stimulation of the celiac plexus in hyperchlorhydria, pylorospasm and gastric ulcer, and other affections in which vagotomy is a factor. His experience with hundreds of subjects examined has demonstrated that this seems to be the most constant of the reflexes, throwing light on the functioning of the vegetative system and on pathologic states in the more important viscera.

- *Enormous Cecal Pouch. A. López.—p. 146.
*Lumbar Puncture in Rural Practice. J. C. Jiménez.—p. 151.
*Pathologic Relations Between the Genital and the Urinary Apparatus in Women. M. Barriagán.—p. 153.

Lumbar Puncture in Rural Practice.—Jiménez deplors the way in which country physicians shun lumbar puncture, thus depriving themselves of this powerful aid in both diagnosis and treatment.

Pathologic Relations Between the Genital and the Urinary Apparatus in Women. In this long article Barriagán discusses the reflex action, the mechanical action and the influence of infection in one of these apparatus on the other. He warns in particular against the danger of injuring the bladder in laparotomies, especially when confronted with a tumor of vague outline. The bladder may be twisted and adherent to the tumor, and injection of a fluid into the bladder, to throw it into stronger relief, may be the only means to differentiate this organ. He says that the frequency is consulted by patients in account of bladder disturbance after hysterectomy, some of mechanical and some of infectious origin. In two cases described in detail the disturbances were due to concretions developing on scraps of suture material. One woman of 50 required lithotomy, and in another case a concretion developed on a silk suture and

was removed three years after the adherent bladder had been injured in removing an ovarian cyst. Normally there is a harmonious homogeneous symbiosis between mother and fetus—the toxins generated by the fetal metabolism being neutralized by the maternal defensive reactions. When this harmony is disturbed from any reason, pregnancy reactions follow from nausea to eclampsia, and the physician should be on the alert to detect this at the earliest possible moment so as to be able to reinforce the maternal defenses. Amblard's formula is a valuable guide for this. In a typical case mentioned, the coefficient was 0.128 but as the patient was put on a milk and vegetable diet for a month it dropped to 0.067, and all the symptoms of pregnancy toxemia subsided. In two apparently normal pregnant women at the third and fifth month the Amblard coefficient was 0.062 and 0.074.

- Cervical Eels: Two Cases. C. Leborgne.—p. 381.
- *Origin of Asthma. J. A. Rampini.—p. 389.
- False Migraine from Brain Tumor in Child. C. Stagno.—p. 407.

False Brain Tumor.—Summarized when practically the same article appeared elsewhere (THE JOURNAL, April 26, 1919, p. 1261).

Origin of Asthma.—Rampini read an article on this subject, "A New Conception of Asthma," at the Pan-American Congress of 1916. He here brings the subject down to date, citing additional testimony for the multiple causes of asthma, toxic, infectious or reflex. Each case has to be studied to learn the special factors involved. Treatment may require measures addressed to lesions remote from the air passages, as he describes in detail, enumerating among others cases of asthma for which lesions in the stomach, liver or bowel were responsible, or the heart, kidney or uterus. In conclusion he emphasizes the importance of tuberculosis in the etiology of asthma. He regards it as the most common cause, and Soca insists that tuberculosis is almost always to be incriminated. The old theory that tuberculosis and asthma are antagonistic is due to the fact that certain asthmatics seem to be refractory to tuberculosis because they have long been infected with it.

- *Deficiencies in Public Health Service. C. H. Hermansides.—p. 990.
- The Specialists and the National Medical Association. H. G. Hinderker.—p. 997.

What Do Unqualified Practitioners Actually Accomplish?—This official committee report is to be summarized elsewhere.

Deficiencies in Public Health Service.—Hermansides remarks that no one can inspect the reports of the Public Health Service without being amazed at the minuteness of the work done, specialist work and consulting work. The laboratories, library and other equipment are at the free service of physicians in general, but few indeed ever think of applying to them, and the service loses a great deal by not keeping in closer touch with the practitioners throughout the country. He continues, "Typhus is appearing at various points, 350 victims at Rotterdam, for instance. The local authorities provided an emergency hospital, but there is no central organization or plan to rid the country of typhus which is now threatening disaster. Two weeks ago, by private initiative, I had the chance to see twenty-five typhus patients at a Rotterdam hospital. Why does not the Public Health Service make it possible for other physicians to get a chance to see this disease so they can recognize it when they encounter it? In dubious cases a consultant should be sent on demand, and physicians at large should be urged to make the demand promptly." "No inspiration or encouragement is given to physicians or local authorities to start at once a de-bussing campaign, without waiting for typhus to get a foothold. The thousands of war prisoners released from Germany in such neglected conditions (*in verzoorgeloos-*

den toestand), passing through the Netherlands, are a constant menace which is not systematically combated."

Hospitalstidende, Copenhagen

- *Transient Myopia. K. K. K. Lundsgaard.—p. 545.
- *Lateral Ventral Hernia. H. Møller.—p. 553.

Transient Myopia.—Lundsgaard reported in 1907 a case of suddenly developing myopia in a man of 40, previously and at the time apparently perfectly healthy. In three days vision returned to nearly normal, the increase of 8.5 dioptries having been corrected down to 0.5 D. Schieck reported not long after a similar but less pronounced case. No others were encountered until recently when Lundsgaard in rapid succession had five patients who presented myopia for the first time and only for a few days. Three of these patients had just or some time before recovered from influenza; two had a rather high sugar content in the blood, but there was no glycosuria. He has also encountered a case in which myopia developed in a man of 50 with high blood sugar content, but in this case the myopia seems to be permanent. In one of the cases astigmatism developed, with myopia in one eye after a contusion. Some change in the curve of the lens is probably responsible for the sudden and brief myopia, and he theorizes to explain the mechanism of this.

Lateral Ventral Hernia.—Møller reports two cases in adults. Fully 50 per cent. of the ventral hernias on record became incarcerated.

June 5, 1919, 81, No. 23

- Can Rupture of a Corpus Luteum Entail Extensive Hemorrhage? C. D. Bortels.—p. 935.

Prophylaxis of Diphtheria in Children's Ward.—Meyer's remarks opened the discussion on this subject at a joint meeting of the Danish Pediatric and the Danish Epidemiologic societies. His tables show that there have been 28 cases of diphtheria develop in the children's ward at the Rigshospital since 1904 in a total of 2,400 child patients, and 4 cases among the attendants. During this period 14 bacilli carriers among the children were detected and isolated, and 13 among the attendants. Among 1,700 new arrivals he found and isolated 21 bacilli carriers. He takes smears from the throats of all new arrivals, and to the routine has recently added smears from the nose. He repeats the tests a week after admittance. His tables show a grouping of cases in some of the years that might easily have run into an epidemic, but this was checked at once. He keeps all new arrivals in a separate room with one or two beds for a few days before admitting them to the general room. He also makes a point of inspecting the throat and mouth, and recently includes the nose, inspecting each child thus daily, and regards this as very important for the detection of acute infectious diseases in their incipience. During the last nine years he has refrained systematically from preventive injections of antitoxin in the service, fearing phenomena of anaphylaxis later; but he makes a point of taking smears from all the patients and attendants when a sporadic case of diphtheria develops. This general smear taking is repeated and the ward kept closed until it is free of carriers again.

THE GRADUATE TEACHING OF OTOLARYNGOLOGY*

L. W. DEAN, M.D.

IOWA CITY

To the members of this section, I wish first to express my sincere gratitude for the honor conferred on me in making me your chairman. I know full well the greatness of the otolaryngologists who have preceded me. While I cannot equal them in ability, I can excel them in estimating the honor bestowed on me. I shall do everything within my power to continue the excellent work of this section.

This session is the Victory Meeting of the American Medical Association. It would be impossible in the brief time allotted even to mention the salient features of the work of members of this section which helped to secure this victory. No other branch of medicine was better administered than otolaryngology; no other was more efficacious in saving the lives of our soldiers; certainly no other did better work in helping in the prevention of contagious diseases. At no time in the history of medicine have the infections of the respiratory tract played such an important part in connection with epidemics. We can well be proud of the work done along these lines by the members of this section. Never shall we cease to honor those of us who gave up everything, and whose work has resulted in such a great credit to us. This work has not been done without the greatest sacrifice. Because of the loss of those who have made the supreme sacrifice, the scientific work of the section will suffer. More than this, the profession of otolaryngology lost some of its leaders who always stood for what was righteous. To me it has seemed impossible that the morale of our specialty should not be affected by the death of these men. It is our duty to remember what they stood for, and see that the ideas which they exemplified in their daily life shall be continued. This is the least we can do to show our appreciation of their sacrifice. Unconsciously we shall honor them forever.

Because of the loss to us of one whose life work has been the development of graduate teaching of the head specialties, I am inclined to make this the subject of this brief address. The work of the late Col. Frank C. Todd had more to do with the advance of the graduate teaching of the head specialties along proper lines than that of any other man in our profession. The work which he began we should not allow to cease. Let us honor him by continuing this great work.

The reconstruction work of the medical service of the army and navy along the lines of otolaryngology will be carried out with all thoroughness by the members of this section.

EDUCATION OF THE OTOLARYNGOLOGIST

The next most important thing to us during the period of readjustment is the question of education of the otolaryngologist.

The undergraduate teaching of otolaryngology can be dismissed with a few words. Its function is to make the medical student conversant with otolaryngology to such an extent that he will know those things that are essential for general diagnosis and therapy.

A second no less important function is to convince the student that work in the otolaryngologic field is so specialized that it should be attempted only by those specially prepared.

The time allowed for undergraduate teaching of otolaryngology is barely sufficient to accomplish these two things. This matter, however, has been taken out of our hands by the Association of American Medical Colleges.

The teaching of graduate otolaryngology, however, is at this time in your hands. The Association of American Colleges is now considering this question of the graduate teaching of this and other branches, and I believe it wise for you to make definite recommendations soon regarding our specialty. I believe any definite recommendations that are made will help materially in solving the problem.

The experiences during the war indicate the necessity of standardizing the requirements for the practice of otolaryngology.

Brigadier-General Munson¹ has reported that at Camp Greenleaf, of those claiming to be otolaryngologists, 70 per cent. were rejected as incompetent. This statement brings to our minds the thought that if the army in order to protect its men found it necessary to reject 70 per cent. of the so-called otolaryngologists, what possible way exists at this time for the laity to protect themselves? How can any one in a strange city, needing the services of an otolaryngologist, tell whether or not he is employing a competent one? This is a most important question and should have a decided bearing on the question of a degree indicating proficiency in otolaryngology.

General Munson also said:

It must be emphasized that the medical officers who finally reached the medical training camps represented much better than the average of the medical profession of the country, for these candidates had been subjected to several processes of elimination. . . . A large proportion of the undesirable

* Chairman's address, read before the Section on Laryngology, Otolaryngology and Rhinology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

1. Munson, F. L. The Needs of Medical Education as Revealed by the War, J. A. M. A. 72:1050 (April 12) 1919.

bles of the medical profession were excluded from service and never reached a medical training camp. The latter, therefore, dealt with an already selected class. That this selected class presented still further professional deficiencies invites reflection on the part of all those in charge of medical education.

He stated that a large number of men actually practicing as specialists in this country, and generally accepted as such, are not duly qualified as the experts they are supposed to be. The latter point is one of special interest and concern to those interested in graduate and specialist education in this country.

In a general way it may be said that the general professional qualification of officers bears a close relation to the educational standard of the schools from which they graduate.

He further stated that in most instances in which a special knowledge was assumed, however, the student claimed to have been actually practicing a specialty.

We have no right to criticize these men. It is our fault that they were deficient in that we have not provided proper facilities for their education. We have not even indicated the length of time that should be devoted to attain proficiency in otolaryngology or the kind of work that should be done.

To overcome this lack of proper knowledge of otolaryngology in these officers, our own Dr. Thomas Harris was selected to establish a school for the teaching of this subject. The excellent work that he did requires no comment. The excellence of graduate work done in the army in otolaryngology is evidenced by numerous recent contributions to the literature of many of our younger men which are excellent research contributions—not merely citations of interesting cases.

Dr. James McKernon feels that many of the inefficient otolaryngologists were the product of short courses. In my own work I find a large number of men seeking advice regarding the study of otolaryngology who are stunned at the suggestion that they devote two or three years in preparation for the work, the impression being that only a few weeks are necessary. We should do something to correct this more or less universal opinion.

It is equally important to the standardizing of graduate work in otolaryngology to create some method of enforcing these standards. Unless the American Association of the State Licensing Boards should become interested in this subject, it will be a very difficult thing to do. The least we can do is to indicate to prospective otolaryngologists what constitutes proper preparation.

THINGS OF IMPORTANCE IN TEACHING

In the graduate teaching of otolaryngology, certain things are of importance. Most essential in the development of the specialist is for him to be so well prepared in general medicine that he will not overrate the importance of his specialty. One of the best things that can be said of a specialist is that he is a good internist. He must be so well versed in general medicine that he will feel the need of the services of the internist and other specialists constantly. He must not feel that because he has disease of the nasal sinuses, and a lesion of the optic nerve, the latter is necessarily the result of the former. His knowledge must be such that he will feel the necessity of reports from the internist, serologist, roentgenographer and others before he can render his patient the best service.

Norval Pierce² has said:

If I were called to tell what I considered the best thing in a medical sense that I got out of my experience at Camp Grant, I would say it is the realization of what efficient results may be obtained when medical experts really work together.

The same condition should come about during the educational period. As I view it, it is very essential for the student to do a large part of his work in hospitals where a large percentage of the special cases are seen by representatives from other departments, dermatology, neurology, psychiatry, internal medicine, general surgery, genito-urinary surgery, etc., and where he sees, as consultant, a large number of cases that logically belong to the other specialties. In this way only will he secure the proper point of view of a specialist.

The greatest danger in specialism, as I view it, is the fact that the specialist may become narrow, and see only his side of the medical problems. During the educational career, everything possible should be done to prevent this. In the seminar work, which should form such an important part of otolaryngologic teaching, fully one third of the topics considered should be borderline subjects, and not those treated in our special textbooks.

The clinical teacher in the fundamentals of graduate otolaryngology must be one who is willing to place the teaching first, and private practice second. The latter part of the work may be given by the great clinicians, who need not necessarily engage in the routine didactic work. The clinical man who teaches the fundamentals must carry out a regular routine work. I do not have reference to the laboratory subjects, anatomy, pathology, bacteriology, etc. Necessarily the courses in the branches must be systematic and complete.

The clinical teacher of the fundamentals of graduate laryngology should spend at least one half day with the student. He should have the regular ward walks; he should supervise the clinical charts; every case the student has in his care he should go over with him; he must conduct seminar work; he must teach thoroughly the diagnostic technic, and he should have these men assist him at the operating table, and then later supervise every move they may make when they are themselves operating. This is particularly a most laborious task. Naturally, no student should be allowed to attempt any operation until he has mastered it in the mortuary. What does the teacher get out of this work himself? I know of two things: First, nothing can influence him more favorably than constant association with a small group of graduate students, answering their questions, and discussing the problems not thoroughly understood today. The teacher who can satisfactorily answer all questions is indeed a rare man. Second, his clinic becomes a real scientific laboratory, and as a rule his charity patients are better diagnosed and treated than the average private patients.

The laboratory work can best be done in the laboratories of our medical schools and universities. Complete systematic courses in anatomy, pathology and bacteriology are essential. The laboratory and the fundamentals of clinical work should go hand in hand. The operative work in the necropsy room must be very thorough in order that no patient when operated on

² Pierce, Norval: *Annals Otol., Rhinol. & Laryngol.* 27: 856 (Sept.) 1918.

shall get anything but the best possible result. The performance of operations on patients by students, not properly prepared and supervised, is a most inexcusable thing.

A man is better qualified for the practice of otolaryngology who has a thorough knowledge of the anatomy and pathology of the subject, with little clinical experience, than one who has had the clinical experience and little anatomy and pathology. Certainly a thorough foundation in anatomy and pathology is necessary. This work should be given by excellent teachers who command large salaries. Proper education in otolaryngology can be given only with a great financial loss to the institution giving it. The conditions necessary can best be met by our medical colleges and universities.

A DEGREE IN OTOLARYNGOLOGY

The establishment of a degree that will indicate to the layman proficiency in otolaryngology is a question that needs much investigation and thought. We should not hurry in this matter.

The report of the Committee on Undergraduate and Graduate Degrees of the Association of American Medical Colleges shows that, at this time by various institutions, several different degrees are given indicating proficiency in public health work. We should early establish a standard degree indicating proficiency in otolaryngology satisfactory to all schools. This can best be accomplished through the Association of Graduate Colleges of American Universities, and the Association of American Medical Colleges. The degree should be granted by the universities and medical schools. In no other way can it be standardized and kept on a high plane. This does not signify that all work should be done in the medical schools and universities. Both the medical schools and our special hospitals should be used for educational purposes. The school granting the degree must be conversant with and responsible for all work done in special hospitals. Credit may be given for work in absentia if done in special hospitals not associated with medical colleges.

The degree should be an earned degree. It should not be granted on a basis of examination alone. At present in various universities the degrees of M.S. and M.A. are given for one year's graduate work in medicine. These are secondary degrees, and as at present granted do not express proficiency in any line of medicine. We should avoid the use of these degrees to signify in any way proficiency in otolaryngology unless the requirements for the granting of the degrees should be greatly increased.

The degree of Ph.D. with the qualifying term, such as Ph.D. (otolaryngology), written in the diploma but not included in the title or degree conferred on the individual, meets with much approval. The Committee of the Association of American Medical Colleges, just mentioned, recommended that the degree of Ph.D. with or without specification of the field of study be conferred for research work done in any of the fields of medicine when under the auspices of and approved by graduate schools of equal standing with those in the Association of American Universities.

The degree of Ph.D. is the highest earned degree. Three years of work is required for it. This is not too much work for those who wish to excel in otolaryngology. Our desire is not to make more otolaryngologists but better otolaryngologists.

This first degree gives the individual not only professional but scholarly standing. The length of time required to secure this degree should not be urged against requiring it, as after the individual has received his M.D. he can make his own way. Naturally, a prerequisite is an academic degree. Not all well prepared candidates for the Ph.D. degree will receive it; hence it seems advisable to grant a second degree signifying expertness in the art of otolaryngology without indicating research ability.

There is now existing a committee on undergraduate and graduate teaching of otolaryngology. This committee represents the American Laryngological Association, American Otological Association, this section of the American Medical Association, the American Academy of Ophthalmology and Otolaryngology, and the Association of Laryngology, Rhinology and Otolaryngology. I would recommend that your representatives on this committee be urged to hasten a definite report regarding the graduate teaching of otolaryngology.

THE DIAGNOSIS OF CHRONIC PULMONARY TUBERCULOSIS*

THOMAS McCRAE, M.D.
AND
ELMER H. FUNK, M.D.
PHILADELPHIA

The recognition of chronic pulmonary tuberculosis is generally regarded as a simple matter in which there is slight chance of error. That this is not always the case is quickly recognized by any one who has the opportunity of studying a series of cases of advanced pulmonary disease. This study is based on our experience in the department for diseases of the chest of the Jefferson Hospital. In this department the dispensary handles all stages of tuberculosis, early and late, but only advanced cases are admitted to the wards. By admitting only these it seemed that we were making the best use of the beds in the effort to lessen infection by isolating patients in the advanced stages. Our admissions come from the general medical clinic and from the tuberculosis dispensary, but a considerable number are accepted on the diagnosis of other hospitals and general practitioners. We have no opportunity to study these cases until after admission. This study is made to check the correctness of the diagnosis of advanced pulmonary tuberculosis as made by many different members of the profession.

It may be asked what difference an error makes if the patient has some chronic disease. In some of the conditions, for example, bronchiectasis, it is evident that no great harm will be done; but, in others, valuable time may be lost and a condition left untreated which might be helped. Syphilis and the presence of a foreign body in the bronchus are examples of such a condition. In addition, such patients are occupying beds which might be more usefully employed. In discussing errors in diagnosis, we must realize that every one makes mistakes, and we should be charitable to the other man concerning those he makes, but very severe in judgment on our own. The important lesson is to try and reduce the number of errors in the future.

* From the Jefferson Medical College.

Read before the Section on Practice of Medicine at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

This report is based on the study of 1,200 consecutive admissions, all the patients coming with a diagnosis of advanced pulmonary tuberculosis. In the series, seventy-two, or 6 per cent., were found to be nontuberculous. There is always a chance of error in a clinical diagnosis, but we have a check in the necropsy results. There were 134 necropsies in this series, and among these it was found that seven patients had been nontuberculous, 5.2 per cent., which is fairly close to the previous figure. Of these seven cases which came to necropsy and were found to be nontuberculous, in five we had made the correct diagnosis; but two went to necropsy with a diagnosis of tuberculosis in which we were in error. These cases are discussed later.

There is an interesting study by Ash¹ on the necropsy findings at the Boston Consumptives' Hospital. In 198 necropsies, twenty-three cases (11.6 per cent.) were found to be nontuberculous; seven of these had been correctly diagnosed before death. He collected a series of 353 necropsy cases from eight hospitals and found that thirty-eight (10.9 per cent.) of these were nontuberculous. The total of this report gives 551 necropsies with sixty-one nontuberculous cases (11 per cent.). The conditions found were: chronic cardiorenal, 27; pneumonic sequelae, 11; neoplasm, 7; aneurysm, 6; syphilis, 4; septicemia, 4; actinomycosis, 1; pellagra, 1.

In our series, the various conditions which were wrongly diagnosed as advanced pulmonary tuberculosis are: cardiorenal, 19; pneumonic sequelae, 9; bronchiectasis, 8; abscess of lung, 8; chronic bronchitis, 6; neoplasm, 5; syphilis, 4; aneurysm, 2; anthracosis, 2; bronchial asthma, 2; empyema, 2; diabetes mellitus, 1; cancer of rectum, 1; foreign body, 1; malingering, 1.

Seven of these came to necropsy (five with a correct diagnosis), the conditions found being: abscess, two cases; cardiorenal disease, two cases, and one each of aneurysm, neoplasm, and delayed resolution in lobar pneumonia. Of the two instances in which cases came to necropsy with a diagnosis of tuberculosis, one of the patients had had chronic lung abscesses, and the other, delayed resolution of a lobar pneumonia.

It is to be understood that there were cases in which these various diseases, with the exception of syphilis and neoplasm, were associated with tuberculosis. We have given only the number of cases in which an error in diagnosis had been made and tuberculosis was not present. The various groups are discussed in detail.

VARIOUS GROUPS

1. *Cardiac and Cardiorenal Disease* (nineteen cases).—These are cases in which a proper diagnosis might give a chance of benefit, in some cases, at any rate. The reasons for error are very evident, and first among them we must put careless or incomplete examination. These are the cases in which there is the least excuse for error. Failing health and strength, dyspnea, cough and the finding of râles in the chest were the features which were wrongly interpreted. A proper physical examination and a study of the sputum should prevent such mistakes. This group took first place in the series of instances collected by Ash. Of the cardiac cases it is of interest to note that fifteen

were cases of mitral disease, in seven, mitral stenosis being present.

2. *Chronic Inflammatory Conditions in the Lungs, Usually Associated with Some Form of Pneumonic Process* (nine cases).—There was usually an associated general bronchitis. It is evident that in this group there are difficult problems, but it may be that because of this difficulty more care is taken. Of these cases, three proved to be unresolved lobar pneumonia, and six were atypical cases of bronchopneumonia. Case 1 is an example of lobar pneumonia in which we failed to make a correct diagnosis:

CASE 1.—W. G., a negro, aged 37, was admitted with a history of cough which for three months had become progressively worse. Three weeks prior to admission he was compelled to go to bed because of chilliness, fever and weakness. His cough became quite severe and was associated with blood-tinged sputum. His best weight was 175 pounds a year before, and for four months he had progressively lost weight until, on admission, he weighed 99 pounds. Examination showed an extremely sick, emaciated negro with signs of consolidation over the greater part of the right lung and scattered, crackling râles throughout both lungs. One sputum examination was negative. A clinical diagnosis of tuberculous pneumonia, in spite of the one negative sputum, was made, because it was thought that the finding of tubercle bacilli had perhaps been missed, but would show on future examinations. The patient died on the third day following admission.

The necropsy revealed the following nontuberculous changes: The right lung was solid except along the anterior margin and extreme apex of the upper lobe, anterior margin of the middle lobe, and a slight fringe at the bottom of the lower lobe. An incision of the organ showed surfaces that were gray, except a small portion of the apex and the base of the lower lobe; these areas were light red, with small, grayish mottlings. The gray areas were firm. The left lung was large, dark in color, and very soft, with decreased crepitation. The incised surface exuded an excess of frothy, blood-stained serum. The pathologic diagnosis (verified by histologic examination) was lobar pneumonia with gray hepatization of the right lung.

Several cases were instances of the slow-clearing basal pneumonia to which much attention has recently been drawn. The good rule that a basal process is rarely tuberculous is often forgotten. Case 2 is typical:

CASE 2.—E. S., a white woman, aged 24, referred with a diagnosis of advanced pulmonary tuberculosis, had lost about 25 pounds in the past year, and two weeks before she began to cough and spit blood. The temperature averaged from 102 to 103. There were signs of acute bronchitis, with many râles throughout both lungs. The resonance was impaired at both bases with suppressed breathing and numerous fine, crackling râles. Sputum examinations were repeatedly negative for tubercle bacilli. After one month her temperature became normal and remained so for another month, at the end of which time she had a febrile recurrence with the same symptoms and signs. The condition again cleared up in about four weeks, and the patient was discharged three months later free from symptoms and signs. During the first febrile period the following roentgen-ray findings were noted: There was a very dense area at the base of the right lung, probably unresolved pneumonia, and another extending from the second to the fourth rib anteriorly and the fifth and sixth posteriorly. The left base showed some clouding but not as extensive as on the right side. The apexes appeared fairly clear.

With regard to the subacute and chronic nontuberculous pulmonary infections, the composite clinical history of a group of these patients is about as follows:

¹ Ash, J. L.: The Pathology of the Mistaken Diagnoses in a Hospital for Advanced Tuberculosis, J. A. M. A. 64: 11 (Jan. 2) 1915.

The patient has a cold with slight fever but continues at work, although he feels ill, or, in more severe cases, may be compelled to go to bed for a few days or a week. A diagnosis of bronchitis or influenza is made. A week or ten days after the onset the fever is less, although there may be an afternoon elevation between 99 and 100. The constitutional symptoms subside, but cough and expectoration continue and, in a few instances, there may be hemoptysis. Examination reveals a more or less constant localization of signs in the lower lobe, dullness, increased vocal fremitus, diminished breath sounds and many fine, crackling râles. Tubular breathing is seldom heard. The sputum examination is negative for tubercle bacilli, but usually shows a larger number of other organisms.

This group has been carefully studied, and the differential diagnosis rests, as Miller states, on the constant localization in a lower lobe, the absence of constitutional symptoms in the presence of extensive physical signs, the absence of tubercle bacilli, and the presence of the organisms of acute respiratory infections, the character of the roentgenogram, and the disappearance of signs and symptoms, in the majority of instances, far more quickly than would be possible in tuberculous lesions of similar extent.

It is of interest that most of our cases of this group came in during the past winter, and this is undoubtedly because of the influenza epidemic. Many errors of the nature described are to be made in the next few years if the experience of the last pandemic is any guide. In the nineties we learned by experience that there were many atypical pneumonias of long duration, sometimes apical, which were mistaken for tuberculosis. In many of these, the question of diagnosis is concerned with the possible lighting up of an old tuberculous process and, in this, the roentgen rays give little help in some cases. We would emphasize the value of time and repeated sputum examinations in making a correct diagnosis in this group.

3. *Bronchiectasis, Usually with Marked Fibrosis* (eight cases).—It is easy to understand the reason for this error if the diagnosis is made on physical signs alone and the sputum is neglected. The study of the sputum should prevent mistakes. We have reported one of these cases² in which the patient had been in three tuberculosis sanatoriums with a diagnosis of advanced pulmonary tuberculosis.

4. *Pulmonary Abscess* (eight cases).—Apparently the general features, fever, emaciation and sweating, with the signs in the lung, were relied on for diagnosis. The examination of the sputum was evidently neglected. Sputum which is persistently purulent and does not contain tubercle bacilli is strong evidence against tuberculosis. In one case of this group we made an error in diagnosis:

CASE 3.—J. D., a white man, aged 32, gave a history of pleurisy three years before, since which time he had a persistent cough with expectoration. Ten months previously he had been in a tuberculosis sanatorium. He had a pulmonary hemorrhage one week prior to admission. He had lost about 16 pounds in weight. He had not had chills or sweats, but had been feverish in the afternoon for some months. The examination disclosed, in addition to the signs of acute bronchitis, evidence of infiltration and cavity formation in the left lower lobe. The sputum examination was reported positive for tubercle bacilli. In spite of the basal character of the

lesion, which our clinical sense told us was against tuberculosis, we made a diagnosis of tuberculosis on the sputum examination. The necropsy revealed a large cavity in the lower left lobe, the outer wall of which was the greatly thickened pleura. The cavity had a fairly distinct wall with a dilated bronchus opening into it. The nonadherent portion of the pleura was covered by a grayish exudate. There was no evidence of tuberculosis in either lung.

5. *Emphysema and Chronic Bronchitis* (six cases).—Reliance on symptoms and signs, together with neglect of proper sputum examination, is the explanation of errors in this group.

6. *New Growth* (five cases).—The same remarks apply as in the two preceding groups. Error is due to lack of proper examination, especially of the sputum. An example is presented in Case 4:

CASE 4.—A. T., a white man, aged 40, was referred with the diagnosis of advanced pulmonary tuberculosis. He gave a history of onset one year before with cough, expectoration, hemoptysis, marked gastric symptoms, and loss of weight. The physical examination revealed marked emaciation, with signs in the chest indicative of consolidation of the upper half of the left lung and scattered râles throughout the entire pulmonary area. The sputum examinations were repeatedly negative. The Wassermann test was negative. A careful study of the history revealed the fact that the gastric symptoms were primary and had been quite marked since the onset. There had been pain after eating, vomiting of brownish material, etc. Examination of the abdomen revealed a small mass in the region of the pylorus which the roentgen ray confirmed as a pyloric tumor. The sputum examinations continued negative, and a diagnosis of secondary carcinoma of the lung was made.

7. *Syphilis* (four cases).—With the present craze, in some quarters, to diagnose syphilis of the lung on rather slight evidence, the number of cases under this heading may seem small; but we are conservative in making this diagnosis. These cases seemed thoroughly proved, and the results of specific treatment were striking. An example is given:

CASE 5.—L. H., a colored woman, aged 27, referred by a general hospital with the diagnosis of advanced pulmonary tuberculosis with laryngeal involvement, gave a history of cough which, for two years, had gradually grown worse, and of expectoration which at times was blood tinged. During the two weeks before admission she had many small hemoptyses. She was weak and had lost a good deal of weight. In the past year she had been treated in a New York hospital for advanced tuberculosis. The physical signs and roentgen ray showed fairly marked bilateral pulmonary disease. The temperature usually rose to about 101 in the afternoon. The sputum was repeatedly negative for tubercle bacilli, and the laryngologist reported that the laryngeal ulceration seemed more like that due to syphilis than tuberculosis. The Wassermann test showed a strongly positive reaction. Following antisyphilitic treatment, the symptoms disappeared, the temperature fell rapidly to normal, the signs became less and, four years later, she is well and working.

8. *Aneurysm, Anthracosis, Bronchial Asthma and Emphysema* (two cases of each).—In both cases of aneurysm the diagnosis, while suggested by symptoms and signs, was made positively only by the roentgen-ray examination. Anthracosis is regarded as tuberculosis much more commonly than these figures indicate, and many such cases sent to the hospital as tuberculosis were recognized in the dispensary and sent to the general wards; so they do not figure here. With any care in sputum examinations, such an error should not be made. The cases of emphysema were not

² McCrae, Thomas, and Funk, E. H.: *Bronchiectasis of the Upper Lobes*, J. A. M. A. 67: 1060 (Oct. 7) 1916.

the ordinary type, but were interlobar and, while difficulty in the diagnosis is understood, sputum examinations would have prevented the error.

9. *Miscellaneous Cases* (one each of diabetes mellitus, cancer of the rectum, foreign body in a bronchus and malingering).—In the first two cases there was some cough, but little else in the way of signs even to suggest the diagnosis. The foreign body was a bullet in the bronchus, the diagnosis being made by the roentgen ray. In several other cases of foreign body which were sent for admission, suspicion was aroused and the patients were not admitted. This figure does not, therefore, give an accurate idea of the number of cases in which an erroneous diagnosis had been made. The malingerer was well up in the symptoms of the disease and was found to have scratched his throat to produce blood-streaked sputum. It was found that he had done this in other hospitals and had been regarded as tuberculous. His object was to evade the military draft.

COMMENT

What were the reasons for these errors? Lack of thorough examination, drawing hasty conclusions from symptoms and signs, and neglect of proper sputum examinations are probably the main causes. Many of these conditions result in loss of weight and strength with anemia, are accompanied by fever, and show signs in the lungs. The great safeguard is proper examination of the sputum. In any patient with marked signs in the lungs and a sputum negative for tubercle bacilli, suspicion of a diagnosis of pulmonary tuberculosis should be aroused at once. Too often a diagnosis is made and no thought given to proving it. How many negative sputum examinations are necessary before tuberculosis can be excluded? Six negative examinations are said to be enough, but we should suggest more than this.

The problem is very different from that concerned in the diagnosis of early pulmonary tuberculosis. Here we should endeavor to make the diagnosis before bacilli are found in the sputum; in the advanced form we should never make a diagnosis of tuberculosis unless tubercle bacilli are found. A word may be said as to verifying a positive result. Of the two cases in which we erred, one error was due to some mistake in the examination of the sputum. A positive result was reported but not confirmed. Either the specimens of sputum or the slides were mixed and a wrong report sent for that patient. There is a rule in the clinic that a positive diagnosis is not to be made on the result of one sputum examination. It must be confirmed. In this case it was not, and that led to error. Had we watched this point more carefully, we should not have had this error in the necropsy series. A positive sputum report is naturally regarded as giving a definite diagnosis; but it is easy to be careless and, in many laboratories, the slides are handled in such a way that a mistake is easily made. This is a point to which more attention should be given. Its possibility is suggested when patients come with a history of one positive and many negative examinations.

It will be noted that there is no mention of the mycotic infections. We have had these in mind as a possible source of error, but no instance occurred in the series so far as we could discover. In this connection, one comment may be made on the possibility of finding streptothrix which has come from the mouth.

If a careful effort is made to clean the mouth thoroughly, the frequency of the occurrence of streptothrix in the sputum will be found to undergo a striking reduction.

The clinical errors in this series could have been prevented by more care and thoroughness. Some of the mistakes, as, for example, those in regard to the recognition of syphilis of the lung, or aneurysm, are readily made and, perhaps, not easy to avoid in the case of a man in general practice; but this cannot be said of the majority of mistakes. There is little excuse for the error made in diagnosing chronic cardiac disease or bronchitis as advanced pulmonary tuberculosis. One of our own errors was made through lack of attention in making sure that our rules as to sputum examinations were followed.

There is a lesson for sanatorium physicians. A number of these patients had been in tuberculosis sanatoriums and always regarded as tuberculous. This was the case with those patients, particularly, who had bronchiectasis. Some of them stated that a sputum examination had not been made, which is difficult to believe, but is supported by the fact that an incorrect diagnosis was made. In any institution dealing with patients with chronic disease, it requires constant effort not to rest content with a diagnosis once made. We are too likely to accept a diagnosis of advanced pulmonary tuberculosis as one not requiring special care to make, and, when once made, not needing revision. How many patients there are today wrongly regarded as having advanced tuberculosis, no one can say; but they are not few.

CONCLUSIONS

1. In a series of 1,200 consecutive cases admitted as advanced pulmonary tuberculosis, seventy-two (6 per cent.) were found to be incorrectly diagnosed.
2. Among 134 cases coming to necropsy, in seven (5.2 per cent.) the diagnosis with which the patients came to the hospital was incorrect, and in two of them the diagnosis was not corrected.
3. The conditions most frequently diagnosed incorrectly were: cardiac and cardiorenal disease (nineteen cases), chronic inflammatory conditions (nine cases), bronchiectasis (eight cases), pulmonary abscess (eight cases), and chronic bronchitis and emphysema (six cases).
4. The diagnosis of advanced pulmonary tuberculosis should not be made unless tubercle bacilli are found in the sputum on at least two examinations.
5. Physicians in tuberculosis sanatoriums and hospitals should take particular care to verify the diagnosis in all patients sent with a diagnosis of advanced pulmonary tuberculosis.

1627 Spruce Street.

ABSTRACT OF DISCUSSION

DR. LEO KESSEL, New York: It is difficult for most the men to understand the readiness with which the diagnosis is made in patients who are supposed to be suffering from advanced military tuberculosis. So much emphasis has been laid on the diagnosis of early tuberculosis that we have lost sight of the fact that it is just as easy to err in advanced cases. Dr. Funk has pointed out the conditions under which these patients are admitted. One of the most important features to lay stress on is the noninflammatory conditions. These patients usually apply for admission to a hospital between January and March. As a rule, they feel compara-

tively well in the summer. A large number of the patients afflicted with this illness have spent years at a sanatorium. They are discharged with the diagnosis of pulmonary tuberculosis, and when a particularly severe winter comes along, they are admitted to a hospital complaining of cough, sometimes also of dyspnea, etc. They are promptly admitted to a department or to a sanatorium. Careful examination of these patients has revealed that the predominating organisms are pneumococci and streptococci and practically all of the organisms are found in the lungs. The physical signs are almost always at the base. The great majority of patients presented signs at the left base, such as dullness, crepitation and diminished breathing. The patient may have fever, and some have bloody sputum, so that it is very easy to make a mistake in diagnosis. Dr. Funk laid stress on the importance of considering syphilis of the lung as one of the possibilities of mistaken diagnosis in these cases of extensive chest involvement. I believe that it has become a fad to make that diagnosis. We have had a large series of cardiorenal cases which were admitted as cases of tuberculosis, and some of these patients have aneurysm. They have pressure on the bronchus with cough, bloody expectoration and fever. A mistaken diagnosis has usually been made owing to the fact that the patients have not been observed with a reasonable degree of care. The other common mistake has been the error of overlooking new growths of the lung, both primary and secondary. We have had patients with metastatic growths of the lung from carcinoma of the prostate sent to us as advanced cases of pulmonary tuberculosis. The one point I should like to emphasize is the importance of careful examination of the sputum of all patients who present physical signs, and to avoid the immediate supposition that there is something wrong when there are signs in the chest.

Dr. JOHN A. LICHTY, Pittsburgh: It is difficult to differentiate between chronic pulmonary tuberculosis and bronchiectasis, and mistakes in diagnosis are frequently made. The after effect of influenza on the lung is such as to simulate pulmonary tuberculosis. This must be borne in mind. Since this epidemic we have all had experience with cases which we would ordinarily diagnose as tuberculosis but which we now diagnose as influenzal lungs. Dr. Roland G. Curtis gave a series of lectures at Philadelphia in 1894 and 1895 in which he spoke of nonbacillary phthisis. Then we were not in the psychologic mood to accept that diagnosis because it was just after we had learned to stain the tubercle bacilli. Today we have exactly the same class of cases following this epidemic as followed the epidemic of 1889.

Dr. F. M. POTTENGER, Monrovia, Calif.: We are missing chronic tuberculosis ten times more often than we are diagnosing other cases as chronic tuberculosis. The postinfluenzal cases are giving us much trouble. It is extremely difficult to determine whether or not a patient presents the results of a postinfluenzal pneumonia or whether it is a case of tuberculosis. To be sure, most of these postinfluenzal cases are basal, but I have seen several of these cases which were combined with tuberculosis. Foci are scattered through the lung that it is easy for influenza to stir up. On the other hand, influenza may localize at the apex of the lung just as well as at the base, and then we think it is tuberculosis. I see many cases of bronchiectasis that are diagnosed as tuberculosis. We cannot say that a negative sputum is not tuberculous. In these cases in which we find no bacilli and in which there is an extensive involvement, we can not say that the case is not one of tuberculosis. Also we find patients who have chronic tuberculosis, with healing, leaving a cavity containing secretion but no bacilli. As a rule, if these patients take cold, bacilli appear. Chronic pulmonary tuberculosis with an abscess in the center of an infiltrated area gives râles. Pulmonary bronchiectasis is of the same type. The tissue adjacent to the lesion may be the seat of a considerable fibrosis, and there will not be many râles. Consequently you will suspect a nontuberculous process in the absence of signs on auscultation. Very often a rhonchus is heard but the signs of acute pulmonary tuberculosis are rarely present.

Dr. A. G. SHORTELL, Albuquerque, N. M.: I want to call attention to the importance of a Wassermann test in the

diagnosis of chest cases. In my own work I found about 10 per cent. positives. I then compiled results of quite a number of other workers, and they averaged about 7.5 per cent. During the war I had to neglect this routine Wassermann, making Wassermans only when the history or some uncertainty made it desirable, and I got only 3.5 per cent. positives. Four out of 1,300 cases is a very small percentage. If Dr. Funk had made routine Wassermans he would have found that 7 or 8 per cent. had syphilis of the lung or syphilis as a complication.

Dr. ELMER H. FUNK, Philadelphia: In regard to the post-influenzal cases, we are going to be at a loss to classify patients who have cough and expectoration. The roentgen ray does not help us much. If this man has not had a previous influenza, I would be inclined to think that the shadow meant tuberculosis. If he has had influenza, he might have a lighting up of a tuberculosis, but the roentgen ray would not help us on that. If a man has a basal lesion, that is good evidence that it is not tuberculosis. In 134 consecutive necropsies on patients with tuberculosis, we have never yet found a single primary basal case; in every one, you could trace out the old lesion to the apex. So that when you get a basal lesion with clear apex, it is fairly good evidence that it is not tuberculosis. Neither can it be said that because the lesion is apical it is tuberculosis. We reported some cases of bronchiectasis without clubbing of the fingers and without fetid sputum. These patients suggested tuberculosis but they were negative for tubercle bacilli. Every now and then you will get an advanced tuberculous lesion which is closed, but the occurrence is rare.

THE RECOGNITION OF TROPICAL SPRUE IN THE UNITED STATES*

EDWARD J. WOOD, M.D.,
WILMINGTON, N. C.

There can no longer be any doubt of the existence of tropical sprue in the United States. While the majority of the cases are occurring in the Southern states, it is interesting to note that one of my series came from New Hampshire, one was seen in Syracuse (a Porto Rican case), and one came from the Johns Hopkins Hospital. It is evident, therefore, that a familiarity with its cardinal symptoms would be helpful to many more in the profession than those of us from the South.

In another communication¹ I attempted to collect all references in the literature to the occurrence of the disease in America. Since 1915, when that paper was written, the evidence has grown that the disease is by no means rare and that the cases are widely distributed. In North Carolina its occurrence is no longer a medical curiosity.

SYMPTOMS OF SPRUE

Sprue is characterized by three groups of symptoms: those of the mouth, the intestinal tract, and the blood.

The mouth symptoms have been painstakingly described by Sir Patrick Manson,² who divides them into seven subheads. His description is too full to allow of even an abstract here. My own observation leads me to avoid too fine a line of differentiation of these symptoms. Suffice it to say that the tongue is inflamed and pink, with congested fungiform papillae, eroded patches and superficial cracks on the dorsum

* Read before the Section on Practice of Medicine at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

² Manson, Sir Patrick: Sprue or Psalosis, *Allbutt's System of Medicine*, Ed. 7, **3**:774.

and edges. Crombie's molar ulcer is frequently mentioned as a helpful symptom, but I have observed it even more frequently in pellagra. The tongue in sprue is quite different from the tongue in pellagra. In the latter disease it will be found more pointed and not so flabby. In sprue, it is very much paler than in pellagra. There is also, in sprue, an approach to the cobblestone appearance which does not occur in pellagra. After a short experience with the two diseases, any observer may expect to make a correct differentiation by examining the tongue alone.

The diarrhea in sprue is the most distinctive symptom. The bowel movements occur from midnight until about 10 o'clock in the morning. There then occurs a cessation until the next day. If the cessation does not occur, there will be, at least, a marked diminution in the number of movements in the afternoon and early hours of the night. The bowel movements are very large, suggesting at once a pancreatic condition. The reaction is decidedly acid, and there is much gas mixed with the feces. Examination of the feces reveals a large amount of fat. The stools are light in color and give a positive reaction for hydrobilirubin. Pratt and Spooner,³ with the Schmidt-Strassburger test diet, found a fat loss of 45 per cent, and a nitrogen loss of 15 per cent. P. H. Bahr,⁴ in his Ceylon cases, found a fat absorption of from 70 to 90 per cent., which is much greater than was shown in our experience. In addition to this failure in the utilization of fat and nitrogen, there are other evidences of pancreatic insufficiency indicated by the thymus nucleus test and the Sahli glutoid salol capsule test.

The question of the relationship of the pancreas cannot be discussed here, but it is hoped that an interest in this fascinating problem may be aroused and that the material so close to hand may be utilized in the solution of an important problem. The difficulties of the problem are enhanced by a marked variation in the degree of pancreatic digestion, and also in the utilization of fat and nitrogen.

BLOOD PICTURE

The most interesting phase of the study of sprue at this time is the blood picture. In a large number of cases the color index is above 1, and a case now under observation gives a persistent index of 1.66. The anemia has always been regarded as secondary, and I have no wish to question this point; but it is important to show how the condition may be confused with pernicious anemia. I believe that many cases of sprue have been called pernicious anemia. On the other hand, some cases of pernicious anemia have been diagnosed as sprue. One such experience has befallen me.

In sprue I have noted the most marked variation in the size of the red cells. There was found in a recently studied case a decided preponderance of oversized cells, as well as numerous dwarf cells. There also occurs poikilocytosis. It was noted that there were many very pale cells in the field when the blood was stained with any of the eosinates of methylene blue. Stipple cells were very rarely found. In the case referred to above, in which the blood was carefully studied on different occasions in many slides, no nucleated red cells were found.

Notes of a case now under observation will be briefly presented, chiefly on account of the blood picture.

REPORT OF CASE

CASE.—Mrs. H., aged 37, the mother of three children, was married to a saw mill worker moving from point to point in North Carolina, and living under rather unfavorable hygienic conditions.

The present trouble is said to have begun at the birth of her third child in September, 1918. She denied ever having had any form of anemia before. Her physician's information was limited because of the fact of her moving about at short intervals from one saw mill to another. Following the birth of the third child she had a rather severe influenza and has never been well since.

Owing to a sore mouth and tongue, in addition to extensive pyorrhea, she was advised to have all her teeth removed, which she did.

Throughout the winter the diarrhea, which was of the maternal character, and the anemia persisted. There seemed to have been only the very slightest variation in the severity of either symptom.

The physical examination was practically negative. The liver dulness was slightly reduced. The spleen was not palpable. The patient had lost some flesh.

The red blood count was 600,000; the hemoglobin, 20 per cent.; the color index, 1.66. No megaloblasts nor normoblasts were found on repeated examination of many slides. There were no stipple cells. There was a marked difference in the way in which the red cells took the stain. This was shown chiefly in numerous strikingly pale cells. There was a preponderance of oversized red cells, the percentage ranging from 25 to 30. The fragility test of the red cells with hypotonic salt solutions showed that hemolysis had begun at the 0.45 per cent. point and was complete at the 0.3 per cent. point. This was regarded as normal.

The white blood count was 3,200; polymorphonuclears, 40 per cent.; large lymphocytes, 16 per cent.; small lymphocytes, 44 per cent. No parasites of malaria were found. The blood Wassermann test was negative.

There was an absence of free hydrochloric acid in the stomach contents, and marked stasis.

The feces were light yellow, and were very acid in reaction. Crystals and droplets of fat were found on microscopic examination, after staining with sudan III. The beef nucleus test showed that while the nuclei of the muscle fibers were in great measure digested, there persisted nuclei which had not been completely digested. The agar tubes of Einhorn failed to give returns from which any conclusions could be drawn, probably because of faulty technique. The three-day test diet was given, and the examination to determine the absorption of fat and nitrogen undertaken; but they cannot be reported on now.

There was no tenesmus or blood with the diarrhea. The movements were for the most part large.

RELATION OF SPRUE TO ANEMIA

Biermer's⁵ original report on pernicious anemia mentioned, as a group of symptoms, digestive disturbances with occasional diarrhea. Elder and Matthews⁶ reported two fatal cases of pernicious anemia following labor. The attack was ushered in with ulceration of the tongue and throat. The work of Hunter⁷ will be recalled because of his rather extreme view that streptococcal infection of the tongue and upper alimentary tract bore a part in the etiology of pernicious anemia. G. A. Charlton⁸ studied the effects of chronic infection with *Bacillus coli*, and produced a very striking anemia, which was characterized by a *pari passu* reduc-

tion in hemoglobin and red corpuscles. He concludes that by subinfection the ordinary organisms of the intestinal tract may produce a very definite anemia.

These instances from the literature are mentioned because our study of sprue has led us to think that it may be a bridge between the anemias experimentally produced by the colon bacillus, and possibly others of the usual intestinal flora, and an anemia which probably owes its origin to a true intestinal disease, one which more nearly approaches pernicious anemia than any of the anemias produced experimentally. We are now preparing for a study of the colon bacillus isolated from the duodenal contents in sprue.

It is worthy of emphasis that the remissions in sprue are as striking as in pernicious anemia. That remarkable recurrence which is so often seen in pernicious anemia, even after years of quiescence, is also seen in sprue.

What the relation between the two diseases is, if any, remains to be seen, but it is not improbable that a more accurate study of sprue will shed light on many obscure corners in the study of pernicious anemia.

There is no longer an occasion to mention the confusion between sprue and pellagra. The matter should be dismissed with a word. If the sprue stool and tongue are considered, even in the light of an absence of the skin lesion, there should be no confusion.

201 Chestnut Street.

ABSTRACT OF DISCUSSION

DR. DOUGLAS VANDERHOOF, Richmond, Va.: Much credit is due Dr. Wood for having called attention time and again to the existence of so-called tropical sprue in the United States. Chronic or recurring diarrhea, that is, characterized subjectively by absence of pain and tenesmus and objectively by presence of blood, mucus and pus in the stools, is generally due to one of four causes: first, achylia gastrica with diarrhea, a matutinal diarrhea. This cause of diarrhea accounts for from 90 to 95 per cent. of the cases of chronic or recurring diarrhea characterized by absence of pain and tenesmus, by blood, pus and mucus in the stools. Second, cases of pancreatic achylia, characterized by absence or deficiency of the pancreatic ferment in the duodenal contents or in the stools, perfectly definite cases, not occurring very frequently but worthy of consideration. Third, the type of diarrhea in pellagra, and fourth, we must consider sprue. Certain symptoms are common to all these four forms of diarrhea, namely, stomatitis, anemia and weakness, and loss of weight; and from these symptoms it is difficult to differentiate between these four forms. Of course, in sprue the patient goes on to extreme emaciation, whereas in pernicious anemia or achylia the patient is not infrequently a well nourished individual. Then, again, the picture is confused by the fact that either a gastric or pancreatic achylia may complicate pellagra or may complicate sprue, and it is due to this fact undoubtedly that so much confusion has existed in the establishment of sprue as a clinical entity. There are certain cases of so-called sprue that are absolutely relieved by the exhibition of pancreatic ferment in the diet. Other cases of sprue are relieved by an autogenous streptococcus vaccine. As to the differentiation of these diseases: In achylia gastrica, the absence of the gastric secretion is characteristic; in pancreatic achylia the deficiency of the pancreatic ferment in the duodenal contents or in the stools is characteristic. In pellagra, the skin lesions and the mental symptoms help, whereas in sprue examination of the stools is decisive. My personal experience with sprue in Virginia and the neighboring states leads me to confirm the opinion of Dr. Wood and others that so-called tropical sprue is a clinical entity, and that it occurs in the United States in individuals who have never been out of the United States.

DR. JOSEPH H. PRATT, Boston: The patients with tropical sprue that have come to America from the West Indies and

from China have had fatty stools. In other words, the diarrhea is a fatty diarrhea. The resemblance of the stools in these cases of sprue to those in complete obstruction of the pancreatic duct is very striking. In three or four cases we did metabolism experiments to determine the amount of fat that was absorbed and the amount of fat that appeared in the feces, and we found that the feces contained so much fat that microscopically they seemed to consist almost entirely of fat. There is no doubt that a great many patients with sprue are coming to this country and cases are developing in the northern states and are unrecognized. Prior to the time that Dr. Wood wrote his first paper there was very little if anything written on the subject of sprue in this country. We should always consider the possibility of sprue in every case of chronic diarrhea with loss of strength and anemia, and examine the stools for fat. The tongue may not be sore at the time the case comes under observation, and the anemia may not be marked but in the cases I have seen, the fatty diarrhea has been the striking feature. I studied very carefully the case of a patient who had not been out of New Hampshire for five years. In that patient the subsequent course and the clinical history were typical of sprue, and if there is one case in the northern states, there must be others.

DR. W. C. ALVAREZ, San Francisco: We see many cases of sprue in San Francisco mainly in people returning from the Orient and India, and I believe that there is something more than the pancreatic lesion present because I have seen pancreatic fatty stools and stools of sprue. In sprue the characteristic thing in all cases I believe is a change of the type of flora in the stools. If you put a sprue patient on a meat diet for a while, he generally improves very markedly. Many patients get well, the bacteria in the stools change, and the stool changes in color. It seems that if it were a pancreatic lesion, the large amount of meat which you feed would not be digested any more than the fat. Take a patient who is comfortable and give him starch, he immediately bloats up with gas if some of those yeasts and moulds are still present. I have seen remarkable cures from the use of vaccine. The strawberry cure is one of the strangest things I have ever seen. Why a man with a violent diarrhea can eat several boxes of strawberries and improve on it is a puzzle. You can differentiate sprue from other types of diarrhea by feeding the patient on a box of strawberries.

DR. EMANUEL LIBMAN, New York: Five years ago I saw a case of secondary sprue in New York. The patient had never left New York City. There was complete achylia and disturbance of the reflexes. Up to that time no cases had been called sprue with a color index above 1. These cases are of importance, and we must diagnose between sprue and pernicious anemia. If you analyze the symptomatology of sprue and pernicious anemia, you will see a close relationship. There is a mistaken idea that in pernicious anemia the symptoms are due to anemia, but if you perform transfusion, you can remove the symptoms, the sleeplessness, the poor digestion, etc., and you can raise the functional capacity of the kidneys, but you do not remove the tongue lesions, the achylia, or the spinal cord symptoms. Evidently an anemia is produced by a toxin which has an affinity for the blood-forming organs and the spinal cord. In sprue there is a toxin which attacks the gastro-intestinal system and the tongue. As to the spinal cord changes, I do not know what they are, but there is an important difference there. If the toxin of sprue is found, it will give a lead to look out for pernicious anemia.

As to the pancreas: I have seen a few cases of sprue and have been struck by the resemblance to pancreatitis and I have decided to find the exact condition of the pancreatic ferment. Meanwhile, Dr. Thomas R. Brown of Baltimore has reported that in one case of sprue studies of the feces had shown that the pancreatic secretion was entirely missing.

DR. M. L. GRAVES, Galveston, Texas: I wish to emphasize the fact that sprue is becoming endemic in this country. Up to a few months ago the only cases of the disease that I had seen in Texas were cases that had been imported from South America and Africa, but recently I saw a case which appears to have originated in Louisiana. An interesting

feature of this case is the age of the patient—9½ years. She presents voluminous stools associated with the organism described by Ashford in the Porto Rico cases. This little child presented an epileptoid syndrome which I have not seen in other cases of sprue. The attacks are without a definite aura and occur with great frequency, from three to twenty during the day, associated with great pallor and great sweating. The organisms have also been recovered from the mouth in this particular case. This relationship of epileptoid symptoms to sprue has not yet been established.

DR. ALFRED T. LIVINGSTON, Jamestown, N. Y.: On my way to Porto Rico a few years ago I happened to have as companions on the voyage two people affected very intensely with sprue. I became very much interested in them, and before we got to Porto Rico I became a patient myself, having very severe hemorrhages of the bladder, with clots. I was taken to the hospital and operated on, but as soon as I was able after that, I had my wife write to these two people to come to see me because I had conceived an idea that I might be helpful to them. The impression made on me was that the condition was one involving a tremendous amount of fermentation. The stools were so horrible that the husband of this lady could not stay in the house while that operation was going on. So having had a good deal of experience with an antiseptic which I had used in my medical work, without the least suggestion of toxic effect, I thought that if these people could be filled with this antiseptic, immersed in it as it were, they might get relief. One of the persons I met on my trip, a man, did not take my advice. He died within ten days. The other person, a lady, accepted the idea, and made a complete recovery. Other sprue patients have also been relieved by the same antiseptic, betanaphthol.

DR. EDWARD J. WOOD, Wilmington, N. C.: Dr. Vanderhoof mentioned the occurrence of pellagra and sprue. I have seen that occasionally. The condition that attracts your attention is the superimposed anemia. In pellagra the anemia is a negligible factor. In pellagra on the three-day diet the utilization of fat and nitrogen is perfectly normal even in extreme cases. In one case I thought I saw some improvement from the use of pancreatic ferment, but I would not dare claim credit for every remedy used in sprue any more than I would claim credit for helping pernicious anemia because it seems to help itself. Dr. Pratt emphasized the fatty diarrhea which after all is the essential characteristic and is the pathognomonic sign of the disease. It would be interesting to know what the chemistry of the feces is. Dr. Alvarez brought up the question of the diet which is one of the vital points in the differentiation. The meat diet of Canty is a pound of beef without any fat, scraped and fed the patient in half portions with hot water. I have seen the hemoglobin double in four weeks by that treatment alone. One of my patients had a high color index just before death. I think it is apt to recur late in life, because the English authorities call it a secondary anemia. The point of vital importance, after all, will be the differentiation between sprue and pernicious anemia. Unfortunately cases of sprue will occur where complete laboratory investigation is well nigh impossible. There is no possible doubt that the disease exists.

Effects of Substandard Diet on German Population—The effects which have appeared relate to all organs. Especially noteworthy is the fact that a tendency to polyuria is present, produced by a very watery diet. Interesting also is the retardation of menstruation in girls and women sometimes for as long a period as a year; the appearance of intestinal intussusceptions; diseases of the genitals in women; besides a great increase in mortality, especially among (a) old people above the age of 50, (b) younger persons, especially women, (c) in the last few years even among schoolchildren, most recently of all, among children up to the age of 6 years. The milk of nursing women is decreasing. The loss of weight among newly born children is not recovered until after many months. Tuberculosis is again as bad as it was twenty-five or thirty years ago.—Dr. Max Rubner.

NEPHRITIS IN THE SOLDIER *

REGINALD FITZ, M.D.

BOSTON

Two types of nephritis were encountered abroad in soldiers during the recent war. Chronic nephritis was a rare disease and can be dismissed without further discussion, as obviously it was to be excluded by a thorough routine physical examination of all recruits before enlistment. Acute nephritis was more common and a greater problem from the points of view of medical administration as a whole, and individual care of patients in particular.

Acute nephritis was not important in warfare until the present time with the exception of the Civil War, when there were approximately 14,000 cases. It was not prevalent in the Franco-Prussian War, the Sino-Japanese War, the Soudan War, the Spanish-American War, or in the South African War. After 1915, however, it appeared among British, French, Austrian and German troops. No figures have been published as to the frequency of the disease in the American Expeditionary Forces. Among the British in 1917 and 1918, as judged by the admissions in two typical general hospitals, it represented about 5 per cent. of all medical casualties sent from the line.

The type of acute nephritis was so well marked clinically that it came to be called "trench" or "war" nephritis to differentiate it from chronic nephritis or acute nephritis of other types. It had four outstanding clinical characteristics: acuteness of onset; the symptom of dyspnea apparently not of cardiac or mechanical origin; the rapid development and disappearance of edema, and the suddenness and frequency of uremic manifestations. The disease affected all branches of the army and was prevalent among officers as well as men. The etiology was not discovered. Many theories as to the cause were put forward, such as exposure, unwholesome drinking water, lead, or the concentrated and high protein diet contained in rations. None were substantiated. No predisposing factors could be demonstrated.

Physical examination of patients with trench nephritis was essentially negative except for dyspnea, high blood pressure and general edema. The dyspnea was not associated with a marked hydrothorax or with cardiac dilatation. There was often a diffuse coexistent bronchitis without signs of consolidation. The blood pressure was sometimes normal or subnormal, but was usually 170 mm. or more. The edema was most marked in the extremities, over the sacrum and chest wall, and in the face. Edema of the genitals occurred with less regularity, and marked ascites was rare. Retinal hemorrhages were not often seen, and true albuminuric retinitis was unusual.

The course of the disease was that of a subacute nephritis tending to last for several months but not to develop into a chronic progressive nephritis. After a period of rest in bed the patient's fluid output rose, and at the same time there was an increased output of salt. Some patients got rid of their edema in this fashion in a few days, while others took several weeks. The excretion of albumin was high at first and tended to increase during the first days of improvement, after

* From the Medical Division, United States Army Base Hospital 5.

* Read before the Section on Practice of Medicine at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

which it fell away to traces and eventually disappeared. The urinary sediment cleared up slowly. At first there were many granular casts, much blood and epithelium. Later hyaline casts appeared and remained for several weeks. A few blood corpuscles seemed to persist for months. The blood pressure fell to normal after sufficient rest in bed, and the dyspnea cleared up promptly. So far as could be discovered, there was nothing specific for trench nephritis in any of these features. They seemed typical of any form of acute nephritis with edema and hypertension.

Among complications, epileptiform convulsions were the most common. These developed in both mild and serious cases, with or without marked edema and with or without extreme degrees of hypertension. They were often associated with mild or maniacal delirium. They were not as alarming as they first appeared and were rarely fatal. Other complications were severe headache and gastro-intestinal indigestion, with nausea and vomiting or diarrhea. Pericarditis and pleuritis were almost never seen.

The eventual prognosis was good, as the mortality in a large series of cases was only 3 or 4 per thousand. The disease, however, did not clear up immediately, and every case was rightly considered as serious, and the patient unfit for any immediate duty.

The treatment for trench nephritis varied in different hospitals. As a routine in Base Hospital No. 5 in Boulogne, a rigid fluid intake and output chart was kept. For the first few days of observation the patient was given a fluid diet of 600 c.c. of milk and 900 c.c. of tea or water. As the fluid output rose, small amounts of bread and jam were added to the diet; and finally when the edema and dyspnea had disappeared, the patients were allowed eggs, porridge, small amounts of chicken, rice and potato, with such desserts as fruits or puddings. An effort was made to avoid diets containing much salt, protein or many calories. The most important single feature of such a course lay in the systematization. The same amount of fluid was given at the same hour every day. When food was added, it was divided carefully into three or four feedings, and each meal contained approximately the same amount of bulk and nourishment. On the whole, the patients did surprisingly well and were very comfortable.

Few drugs were used. Morphin or codein was useful for controlling cough, dyspnea or severe headache. Purgation was avoided as being liable to cause indigestion, and the bowels were regulated with enemas or mild vegetable cathartics. No patients were sweated. A few were given diuretics, but the results obtained were inconclusive. No effort was made to lower blood pressure, as it was difficult to obtain evidence that hypertension alone caused symptoms.

Bleeding seemed efficacious in stopping convulsions. In certain cases, 600 or 700 c.c. of blood were withdrawn, with immediate apparent relief. This procedure next to systematic dietetic regulation seemed most important.

The patients were sent to England on a hospital ship as soon as possible. They all traveled well and seemed to be unharmed by the trip.

The ultimate course in treatment consisted in managing the cases of trench nephritis as though they were cases of chronic nephritis. The diet was gradually made more liberal. After the edema and albuminuria disappeared the patients were allowed to get up, and

were sent back to duty or were discharged from the army as unfit after a period of observation lasting for several months.

On the whole, the problem of nephritis in the soldier was essentially that of the treatment of trench nephritis. This was a type of acute nephritis of unknown cause and of remarkable frequency. It was characterized by its suddenness of onset, the symptom of dyspnea, the rapid occurrence and sub-sidence of edema, the commonness of uremic manifestations, and its low mortality. Clinical study of cases did not demonstrate anything specific as to the nature of the disease. Good results in immediate treatment were obtained by bleeding in the case of patients having convulsions, and by the systematic regulation of food and fluid intake in the less serious cases. The ultimate treatment was that of chronic nephritis.

The disease was serious from a military point of view, as it caused many casualties. However, even very sick patients stood a short journey well so that they could be sent promptly from the line to hospitals outside the zone of advance.

At present it appears that trench nephritis tends to heal and not to develop into a chronic progressive kidney disease. It will be necessary to follow cases for a much longer time than has been heretofore possible before this opinion can be established as fact.

ABSTRACT OF DISCUSSION

DR. HAROLD FEIL, Cleveland: Approximately 100 of these cases have been casualty cases. There has been one striking point and that is the persistence of the hematuria and albuminuria without edema. These patients all resisted treatment in the hospitals for weeks and most of them have been discharged from the army for disability. All these cases were observed for a period of six months or more.

DR. E. P. JOSLIN, Boston: In the absence of Dr. Horace Gray and Major Vandever, I would say for them that each had a large series of similar cases under their supervision, and they have attempted to carry out what Dr. Fitz has suggested, i. e., to follow up the course of each case for several years. These gentlemen, who have worked at Vichy and Mesves, respectively, have collected the addresses of all these men, their records in the army, the names of their physicians, and hope to report on their condition later. As others have collected data of this description we should eventually have interesting facts relating to the after effects of this type of nephritis. In general, the innocuousness of the disease at the time of its height was obvious. Our patients at Mesves certainly did very well. The point was also obvious that these cases could be found if one looked for them. Following the influenza epidemic, a systematic examination of the urine of every man at the center was made, and then the cases promptly came to the fore—cases that would otherwise have been overlooked.

DR. H. E. JONES, Roanoke, Va.: I would like to ask the doctor a question: He did not give the type of the cases, except to state that chronic interstitial nephritis was absent. I would like to know what type of the disease he found among those cases of nephritis; that is, whether acute and chronic parenchymatous, or glomerular and tubular forms of the disease.

DR. HOMER F. SWIFT, New York: Following our army through the active fighting period, seeing many troops that were evacuated from July to November, we saw very few cases of this type go through the trenches when men were living under trench conditions. When our army got up into Germany and the men were living under better conditions, we saw more cases of nephritis, described as trench nephritis by Dr. Fitz. Perhaps, the influenza epidemic had something to do with it, but these patients did not give a history of having had an influenza infection.

DR. REGINALD FITZ, Boston: In answer to Dr. Jones, all I can say is that the clinical picture of acute trench nephritis was quite different and distinct from other types of nephritis. In addition there were cases of acute nephritis following tonsillitis, other infections or surgical conditions with marked albuminuria but without edema, hypertension or the dyspnea which was characteristic of the trench nephritis type.

A NEW METHOD FOR TYPING PNEUMOCOCCI BY THE USE OF BLOOD*

LEON LOEWE, M.D.

SAMUEL HIRSHFELD, M.D.

AND

KAUFMAN WALLACH, M.D.

NEW YORK

Because of the disadvantages known to be inherent in all the methods used for typing pneumococci by means of sputum or urine, we attempted to devise a method which should be based on the use of the blood of the patient. We finally adopted the procedure described herein. It had been pointed out by Rosenow,¹ and later by Longcope,² that pneumococci produce a coagulum when grown in the serum of patients suffering from pneumonia, the clot formation being due to the production of acids, probably from glycoproteins, in the serum. This property—manifested in a different way—we have found to be specific, not only for pneumococci as a group, but also for the various pneumococcus types. A full discussion of the theory of the reaction is reserved for another time.

PROCEDURE

Ten c.c. of blood are drawn with sterile precautions into test tubes containing a few crystals of potassium oxalate (sufficient to prevent clotting). The blood is then shaken with pure fresh ether, added in small, successive amounts, until the red cells are completely laked. The laked blood is transferred to a sterile centrifuge tube and centrifuged at high speed for five minutes. The disk of red cell shadows which collects at the surface is removed with a heated platinum loop. With a sterile pipet, 0.3 c.c. of the laked blood is placed in each of four sterile stoppered tubes 0.8 by 13 cm. To each of the first three is added 0.5 c.c., respectively, of saline emulsion of proved Type I, II and III pneumococci grown on glucose serum agar. The fourth tube constitutes the control. Sterile physiologic sodium chloride solution is added to all tubes, sufficient to make up to 1 c.c. Sterile pipets are used throughout. All tubes are stoppered and placed in a water bath at a temperature of 37 C. until the color change appears.

COMMENT

The reaction consists in the formation of hemoglobin derivatives, mostly methemoglobin, which impart to the tube an unmistakable brownish-red color. The final result is a dark brownish-red, gelatinous clot. The chemistry of the reaction has not been fully studied. It is hoped, by spectroscopic means, to discover initial changes and thus shorten materially the time of the reaction. The reaction, as now determined by the naked eye, has been noted as early as after two hours. The average time for appearance of color change is from six to eight hours.

Certain precautions must be observed: The blood should be tested as soon as possible after withdrawal from the vein. Clotted blood should not be used. The ether should be free from alcohol, poured fresh from closed containers. Saline emulsions of actively growing strains of pneumococci, grown on glucose serum agar, should be employed. Strains that have been artificially cultivated for some time and are growing poorly have delayed the reaction, and may even fail to produce any change.

TESTS

Under the kind supervision of Dr. E. Lebman studies were made on fifty-two patients. The tests in forty-nine of the cases could be confirmed by agglutinin reactions made on organisms isolated from sputum, lung puncture, or both. The tests on the remaining three patients are not checked up with agglutinin reactions, no sputum being available at the time (from twelve to fourteen days after the crisis). These tests are included to show that the reaction apparently does not persist after the crisis.

The forty-nine cases corroborated by agglutinins are divided as follows:

- Group I, seven cases (14 per cent.).
- Group II, eleven cases (23 per cent.).
- Group III, nine cases (18 per cent.).
- Group IV, eighteen cases (37 per cent.).
- Mixed infections, four cases (8 per cent.).

The following mixed infections (as shown in the accompanying table) were disclosed:

Case 4: Types I and II: Agglutination tests on organisms isolated from sputum proved these to be Types I and II.

Case 15: Types I and III: A Type III organism was obtained from sputum; a Type I organism, from lung puncture.

Case 23: Types I and III: The sputum yielded a Type III organism. A lung puncture was unreliable (clumps being present in all tubes).

Case 33: Types I and III: A Type I organism was obtained from sputum; a Type III organism from lung puncture.

It may be inferred that, in some cases of Type I pneumonia, serum therapy may have been unsuccessful because of the presence of unsuspected mixed infections.

Tests on several patients were repeated at intervals to establish the persistence or disappearance of the reaction. In three instances (Cases 34, 42 and 43) the reaction disappeared after the crisis. The three cases mentioned above, in which tests were made from twelve to fourteen days after the crisis, proved to be negative. A result was obtained as early as the second day. There was no opportunity to make studies on the first day of the disease.

Control tests, on patients suffering from diseases other than pneumonia, were uniformly negative.

COMPARISON WITH AVERY TEST

Avery and precipitin tests were made in practically every case. There were twelve instances in which our test proved the presence of organisms of Types I, II and III (confirmed, as stated above, by agglutination tests), in which the Avery test gave a negative result. In this group of twelve cases, two were instances of mixed infections, one case showing Types I and II, and the other Types I and III. In one instance, our test showed the presence of infection by Types I and III; agglutination showed the same; the Avery and

2. Longcope, W. T.: *J. Exper. Med.*, **7**: 626 (Aug. 25) 1905.

precipitin tests showed Type III only. In one instance the agglutination method and our method showed the Type III organism; the Avery test was negative, but the precipitin test gave a reaction for Type III. There was the same experience in another case of Type I infection.

COMPARISON WITH PRECIPITIN TEST

The test was in agreement with the precipitin reaction (when the latter was present), with the following exceptions:

Case 31: Our test showed Type IV; precipitin, Type II.

Case 36: Our test showed Type IV; precipitin, Type III.

Case 37: Mixed infection. Our test showed Types I and III; Avery test, Type III only, and precipitin test, Type III only.

Case 46: Our test showed Type III; precipitin reaction showed Type II.

The accompanying table gives the data from some cases of special interest.

* Sputum unobtainable.

ADVANTAGES OF THE METHOD

1. It is simple.
2. The reaction, when it occurs, is unmistakable and persists.
3. From 5 to 10 c.c. of blood are practically always obtainable, whereas satisfactory sputum is often not available, especially in early stages of the disease.
4. A reaction with blood is obviously more accurate than one depending on sputum, in which contact types may be present.
5. Mixed pneumococcus infections can be determined.

Studies will be extended to establish the possibility of specificity in other infections.²

3. Since this article was written, a positive Type I test was found in a case which proved to be peritonitis due to Type I pneumococcus.

EPIGASTRIC HERNIA IN THE SOLDIER

J. N. HALL, M.D. (DENVER)

Major, M. C., U. S. Army; Consultant in Internal Medicine to the Army Hospitals in Mississippi, Louisiana, Oklahoma, Arkansas and Texas; Chief of Medical Service, Base Hospital

CAMP LOGAN, HOUSTON, TEXAS

There is such a general failure on the part of physicians to realize the importance of the small epigastric hernia, with an even greater failure to recognize the hernia itself, that I wish to report a typical instance with operation, and to speak briefly of six other patients operated on in this base hospital. I shall also call attention to four other cases which either came to my attention elsewhere or were cases in which diagnosis was made and operation performed by surgeons who had, in their work here, come to recognize the importance of these trivial-appearing hernias in causing obscure abdominal symptoms.

Let us say in the beginning that there is no lack of textbook description of the hernia. Berger¹ found 137 in 10,000 individuals (120 males and seventeen females); Macready found thirty-eight cases of epigastric hernia to 19,341 cases of inguinal and femoral hernia, but he obviously overlooked all but the relatively few which are actually obtrusive in appearance. In our "recruit mill" at this camp, we have found them by the dozen, so commonly, in fact, that we have made no note of them unless they produced symptoms, and but few of them do. Only seven have been accompanied by sufficiently severe symptoms and signs to lead us to advise operation.

These hernias generally occur, as stated in most textbooks of surgery, in or near the central line in the space running 2 to 3 inches upward from the navel. Multiple hernias are not infrequent. Keen described four varieties:

1. A small mass of subperitoneal fat without any sac.
2. In addition to the subperitoneal fat a process of parietal peritoneum attached to it without any contents.
3. A sac containing omentum (omentalocele).
4. A sac containing intestine.

An ordinary lipoma may be found in the epigastrium, but it is more movable than the hernia, and is not tender.

If the opening of the sac is of some size, the contents may increase when the patient coughs. The orifice is generally so small, however, that it is probably in less than 10 per cent. of the cases that this sign is observable. Bergman states that the majority contain omentum and transverse colon. This is certainly an error, for of the many score that I have seen, perhaps only half a dozen contained any part of the bowel. The fault with all the statistics lies in the failure to recognize the minute hernias, of the size, say, of a shirt button. There are twenty of these to one of the size of a filibert, and they are too frequently entirely overlooked.

The hospital for the ruptured and the crippled has found no such conditions as Bergman² has mentioned.

Symptoms.—Perhaps in 80 per cent. of the cases there are no symptoms. These are in general the ones in which no true omentalocle exists. When a bit of omentum actually comes through the minute orifice,

1. Berger, in Keen, W. W.: *Surgery: Its Principles and Practice*, Philadelphia, W. B. Saunders, 1907.

2. Bergman: Quoted by Keen (Footnote 1).

often from 1 to 4 mm. in diameter, it generally becomes fast, cannot be reduced, and by dragging on the omentum causes symptoms which I should place thus in the order of their importance:

1. Pain or troublesome discomfort.
2. A feeling of dragging.
3. The ulcer syndrome, sour-stomach, occasional nausea, even vomiting, distress after eating, with periodic exacerbation of all symptoms, and even attacks of colic.

SIGNS

There is a bulging in the epigastrium, such as might result from the subcutaneous insertion of a small button. This mass occurs in these cases with symptoms of great tenderness on pressure, and is occasionally reducible; in that event, reappearing when the patient coughs.

Sharp pressure causes the patient to double up to escape the pain. In two or three instances, notably in one of a man with gastric ulcer, I found what I have called the "electric bell reaction." A touch on the hernia causes instantaneous belching—a quicker response than one would believe possible.

The definite association between epigastric hernia and gastric ulcer has long been known, but is not so widely recognized by internists as it should be. A patient receives no benefit from an operation for ulcer if such a tender hernia is overlooked. As I have elsewhere stated,³ the explanation probably lies in the long continued reflex irritation of the stomach by the omental "drag," so that hyperacidity and ulcer follow, as in chronic appendicitis.

REPORT OF CASES

J. H. S., a young soldier, was sent to the base hospital, Camp Logan, from the stockade, in which he had been confined for being absent without leave. He complained of constant indigestion, gas, pain, sour stomach and so much distress that he could not eat. He had been in another base hospital for the same trouble.

I found a very tender omentocoele 3 mm. in thickness and 1.5 cm. in diameter, and recommended immediate operation, believing it to be the seat of all his trouble. There were no signs of chronic appendicitis, ulcer or gallbladder disease. Three days after the operation the patient asked why the omentocoele had been overlooked at the previous hospital, "for," said he, "I now feel well for the first time in years." It was that constant, nagging pain that made me so cantankerous that I went absent without leave and, as a consequence, was put under arrest.

He was discharged well in a few days, with a recommendation that his sentence be suspended, as he was more of an invalid than a criminal.

In six similar cases, in only one of which did the sac contain part of the bowel, operation was performed here with perfect results. The surgeon who assisted in the first case was called as a witness in court to his former home. Learning that his associate had a patient with indigestion who failed to respond to any treatment, he examined him, found such a hernia, operated the next morning, and showed me a letter after he returned, stating that every symptom had disappeared by the fourth day.

Another young surgeon was ordered to a distant base hospital, and recognized such a hernia in a case of an officer at the time of his third admission for some acute abdominal disease, but was unable to convince the chief of medicine that the hernia was the cause of the trouble. On the fourth admission, a few weeks later, he talked so convincingly to the chief surgeon that the patient was operated on, and, what is more important, has remained absolutely free from symptoms ever since.

At his quarters in Houston, I saw a young officer with a violent attack of colic, his organization surgeon believing that he had a partial obstruction. His epigastric hernia was one of the most tender that I have ever palpated. He had been examined repeatedly in one of the most famous of eastern hospitals, with free use of the stomach tube and of the roentgen ray, but without definite diagnosis and, obviously, without any critical examination of the epigastrium. He is preparing to go to the hospital for operation at this time. The very fact that a two weeks' course of investigation, with every modern appliance, failed to show any organic digestive disease leads me to believe that his symptoms will all clear up with the operation.

I have just examined, in another hospital, a patient who has had his appendix removed and his gallbladder drained, with no benefit, and who has just such a tender hernia. This patient is to be operated on at once.

CONCLUSIONS

Physicians should examine with special care for epigastric hernia in every case of digestive disease. If a hernia is found, the opinion of a surgeon should be obtained as to the advisability of operation, unless it is clear that the hernia is without symptoms. These hernias are so minute and unobtrusive in many cases that we may safely say that the failure of the average physician to find them in possibly about 1 per cent. of the subjects examined is to be taken as evidence that the examination was made without sufficient care. Since less than a fourth of these hernias are associated with any digestive disorder, the question of operation arises in only a minority of cases; but it should, nevertheless, receive the most careful consideration. The surgical operation involved is trivial in comparison with the importance of the results commonly obtained.

HEMORRHAGE AND BLOOD TRANSFUSION IN THE WAR*

BERTRAM M. BERNHEIM, M.D.

BALTIMORE

Among the advances in medicine and surgery wrought in France during the war was the forcible demonstration of the great usefulness of blood transfusion; not only that, it was shown also that thus far nothing has been found to take the place of blood, once a hemorrhage has passed beyond the limits of safety.

This war development is of real significance for, despite efforts to popularize blood transfusion, despite all the brilliant advances of recent years made in this line of work and the reports of innumerable lives prolonged, and lives saved, by its use, there always existed in the profession generally an apathy toward it, a skepticism not only as to its efficacy, but also as to its need. How often have we been told that it is the rarest thing for a patient to bleed to death! The woman suffering from ruptured ectopic pregnancy never passes away from loss of blood—the bleeding gastric ulcer never bleeds till actual exitus. The torn blood vessel of a mangled limb always becomes twisted and plugged; so bleeding from it ceases. And after all, so we were told, a salt infusion or a gum infusion is all that is needed—urgent cases may, perhaps, demand the introduction of the solution

* Read before the Section on Surgery, General and Abdominal, at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

by way of the veins. But, in either event, they will do all that blood will do.

Would that this were so! The number of American dead populating French cemeteries would be reduced quite considerably and the feeling of animosity toward those responsible for the ill-directed, albeit sincere, efforts to introduce gum solution into the treatment of hemorrhage and shock in the battle-wounded would be less keen. The theory was, as I understand it, that the solution of gum acacia possessed all the powers of salt solution for combating shock and refilling blood vessels emptied as a result of hemorrhage. But this was not all: It had a further advantage over salt solution—an advantage approximating even that of blood—namely, the power of sustaining a rise in blood pressure and of remaining within the confines of the blood vessels.

By way of explanation to those who perhaps are not familiar with the sedative degrees of efficacy of salt solution in blood it may be said that in cases of extreme hemorrhage and shock, while salt solution may relieve the condition, it has little sustaining power, chiefly because it rapidly passes out of the blood vessels into the surrounding tissues by osmosis. Blood, on the other hand, has real sustaining power because of its oxygen-carrying properties and its ability to remain intact as a circulating medium. It goes without saying that any medium possessing such attributes, and of a harmless nature—as was said to be true of gum solution—would have been of extreme, really untold, value in the treatment of wounded men. And it was quite in order to try it out. That the studies were, apparently, not carried out with an open mind, that overwhelming evidence against the solution was not sufficient to cause its abandonment, instead of promoting futile efforts to improve it, is greatly to be regretted. It would perhaps have been unfair to demand that when gum solution failed to measure up to expectation no effort should have been made to improve it—the probabilities are that Dr. Cannon and his co-workers felt that the medium had so much to commend it that further efforts were justified. I can only say that with its initial fall from grace, there arose a fear of it and a prejudice against it of such widespread proportions that it never had a chance afterward. Besides, we were at war, our troops were engaged in actual battle, the wounded were coming in by the hundreds and thousands: this was no time for further experimentation. All the efforts of the shock teams, surgeons, physicians and nurses should have been concentrated on salt solution and blood transfusion, the efficacy and the limitations of which we already knew. It is my opinion that if one-half the energy and time that were spent on gum solution had been spent on efforts to get blood and secure donors, we would have more to show for our efforts. Salt solution was practically always at hand—I say practically, because the strain and the stress were so great, at times, that even this simple remedy was not to be had; so we needed, chiefly, a more intensive effort to secure blood—to be used only in those cases in which salt failed to help.

When my attention was called to the fact that patients who had been given gum solution were failing to react, that in certain instances the blood pressure not only failed to show the expected rise, but actually fell, that the fluttering pulse failed to steady and that the depression even had a tendency to become more

alarming than it already was, I suggested, when my advice was asked, that salt solution be given instead of the gum, and that more intensive efforts be directed toward securing blood for those most in need of help. The results were gratifying. It was possible to secure blood oftener than one would imagine, and not from the hospital personnel, either. I am opposed to using these self-sacrificing, overworked persons, even when they volunteer. Passing troops, billeted troops, the lightly wounded, patients with fracture, gave willingly of their blood.

Even so, the number of lives thus saved, compared with the number that might have been saved, was small—and all because blood in bulk was not obtainable, and salt solution, in many cases, would not answer the purpose. I am confident that the high mortality in certain types of cases would have been reduced materially had it been possible to give the patients even small quantities of blood. This is particularly true in the case of those compound, comminuted fractures of the femur in which the patient came in severely shocked by loss of blood, pain, hunger, fatigue and delay in getting him back to the base. The splints were usually properly applied. Salt solution overcame the shock; but because too much had been expected of it, and because blood was unavailable, results were too often fatal in spite of immediate operation.

I recall the case of that man who came in almost lifeless, his left femur shattered in its lower third by a through and through shell fragment. For twenty-four hours he hung between life and death, but as the result of the most judicious use of salt infusions he gradually picked up until operation was considered feasible. A further delay of twelve hours would have been better, but he began to show definite signs of gas infection, and it was then or never if an operation was to be performed. He died eighteen hours after it. If we could have given him 400 c.c. of blood during the operation, he would surely have survived.

I could cite numbers of cases like the one just mentioned, but there is little to be gained thereby. We came to fear this type of case more than others. At times it was impossible to delay operation a moment, owing to the fulminating gas infection which was so prone to develop. Salt solution to the extent of 500 or 1,000 c.c. would be given in the shock tent, a bit of heat applied, and the operation performed. When we had blood, it was customary to give it just as the operation started, in order to tide the patient over; and those who received it invariably did better than those who did not. A case in point is that of a sergeant who came in with an arm shattered, a leg hopelessly injured, and his remaining hand badly torn, one of the most battered-up men it has ever been my pleasure to see live. He too was worked over for twelve hours, at the end of which time some blood was given him. He was put under a light ether anesthesia, and one surgical team removed the arm while another took off the leg. A few days later he had to be put to sleep again to have his right hand cleaned out, his condition at the primary operation having been such that it had to be left untouched.

Another case has always stood out in my mind: A very young trooper was brought in—the instances I am citing occurred during the second battle of the Marne—with his left leg hanging by some loose tissue, the whole wound area filled with dirt and grass and

creating a strong suspicion of a gas infection. His condition was so critical that a member of the shock team attached to our outfit, seeing him lifted out of the ambulance and recognizing the urgency of aid, had him carried directly to the operating room. Any kind of operation then would have meant death; so while he was being given 500 c.c. of blood, which were, fortunately, obtainable, I simply removed the foot with one stroke of the knife and put on a bandage—trusting to luck concerning later developments.

It was remarkable how that boy picked up. Within a few hours, aided by hot water bottles and some hot drinks, he had taken a new lease on life. Nor did he slip back in the slightest—even when, twenty-four hours later, the signs of gas infection were unmistakable. He withstood an amputation above the knee without a quiver and, a few days later, was evacuated to the rear, a well, happy boy, smoking the inevitable cigaret. I could cite other instances like this one, equally gratifying; but one example is as good as a dozen in the same class of cases.

So much, then, for the acute hemorrhage and shock of the battle casualties. The need for blood was great and urgent; the supply, pitifully small. Substitutes were tried and found wanting. Further to the rear, where conditions were a bit less strenuous than in the forward areas, it was possible to secure blood more often, and in greater quantities. Thus, in the base hospitals, a great light was shed on the value of blood transfusion in the anemias secondary to battle wounds. These were very common and most distressing. The men would lie pale, inert, unable to eat, nervous, day by day slipping back just a little, while their wounds not only failed to heal but became increasingly dirty, until all bodily resistance being finally overcome, septicemia ensued, and death resulted. Particularly was this true of bone and joint cases.

We transfused a number of these men, and in nearly every instance a prompt improvement followed. One of them had a huge wound of the buttocks with a great area of bone involvement—always a sad condition. He was having rough going until he got some blood, after which his improvement was rapid and continuous. Another man had a big thigh wound and a septicemia—*staphylococcus*, I think. He overcame the septicemia, as many did, but his anemia was so profound that he did not improve. With two or three doses of blood, however, he took on renewed life and finally recovered, though the leg had finally to be removed. Still a third, and a most remarkable demonstration of the efficacy of blood transfusion, was that of a young lieutenant of aviation who, being wounded through the chest, crashed to earth, sustaining a compound fracture of both bones of his right forearm, a similar condition of the bones of his left lower leg, and a compound fracture of the bones of his right foot. Two months later, when I saw him, he was a mere skeleton and, in addition to his fractures, had three intractable bedsores and a knee joint involved in a metastatic infection necessitating the turning back of the patella. It was clearly a case of too much absorption from too many foci of infection. In all, this man received four transfusions. After the second, his right leg was removed just above the knee for, with the foot hopelessly crippled and the knee joint badly infected, it was simply pulling him down without offering him anything in case of his recovery. The last two started him on the road to

recovery. He was far from a well man even when he reached America; but without those transfusions his chances for life would have been nil. These three cases, each one of a different type, are sufficiently illustrative to prove the efficacy of blood in aiding the recovery of the battle-wounded.

At my suggestion, the sodium citrate method was adopted by the Medical Department of the American Expeditionary Forces as the only method of blood transfusion to be used. The reasons for this are so obvious as hardly to need explanation. Its simplicity, its elasticity, the fact that it could be employed under circumstances that precluded the use of any other method, all combined to make it the one procedure of election. At my further suggestion, all transfusion work in France was turned over to the medical men. Thus it happens that many men have obtained a wide experience in blood transfusion who, in civil life, had had no opportunity to familiarize themselves with it. A brilliant page in the history of blood transfusion was written in France. Let the physicians who wrote it there expand the chapter here.

THE COURSE OF EVENTS IN SECONDARY WOUND SHOCK *

W. B. CANNON, M.D.

George Higginson Professor of Physiology, Medical School of
Harvard University

BOSTON

In the issues of *THE JOURNAL* of February 23 and March 2, 1918, there was published a series of articles by Cowell, Fraser, Hooper and myself which described certain clinical observations that we had made on soldiers who suffered from shock and allied conditions. These observations confirmed earlier reports on the persistent low arterial pressure, the rapid pulse and respiration, and the lowered body temperature of the shock state; they also revealed a concentration of corpuscles in the capillaries, a reduction of the alkali reserve corresponding in general to the degree of lowering of arterial pressure, a marked sensitiveness to ether or chloroform anesthesia, and a tolerance of nitrous oxid and oxygen as an anesthetic. On the basis of these facts a definition of traumatic or wound shock might be offered; it is a general bodily state occurring after severe injury and characterized by persistent low arterial pressure, rapid pulse, pallor or slight cyanosis, sweating, superficial rapid respiration, and usually by a dulled mental condition.

EXEMIA AS A CAUSE OF LOW PRESSURE

Among the articles in the series above mentioned was a theoretical discussion of the nature of wound shock, in which the low blood pressure was regarded as the central fact of the fully developed complex.¹ Reasons were given for refusing acceptance of the acapnia theory and the nerve exhaustion theory of the low pressure. The factors determining arterial tension were then analyzed, with the result that the low pressure was ascribed to "exemia"; that is, a

* Read before the Section on Surgery, General and Abdominal, at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

¹ Cannon, W. B.: A Consideration of the Nature of Wound Shock, *J. A. M. A.* 70: 611 (March 2) 1918.

temporary lessening of the volume of circulating blood, though not a loss of blood from the body. The possibility that the acidosis of shock, if carried to a sufficient degree, might play a rôle in causing further exemia was considered, but the occasion for the primary fall of pressure was left unsettled.

Shortly after the foregoing articles were presented as a report to the Subcommittee on Shock of the English Medical Research Committee, opportunity was offered at University College, London, to cooperate with Prof. W. M. Bayliss in an experimental analysis of the phenomena which had been observed clinically. Unfortunately, that work was cut short by military necessities, and the possibility of resuming it did not arise until the establishment of the Laboratory of Surgical Research of the American Expeditionary Forces at Dijon, France. Much that appears later in this report has come from observations made in London and from observations made by the group working at Dijon.²

PROPER EVALUATION OF THE DIFFERENT AGENTS IN SHOCK

That the phenomena of shock require experimental analysis is clear from a consideration both of its inherent complexity and of its attendant conditions. Shock has long been one of the great mysteries in surgery, and because of associated hemorrhage and infection there is usually much difficulty in assigning proper values to the different agents which might produce the general state of depression. No doubt hemorrhage may have an important part in the development of this state, and infection likewise is important; but there are recorded cases in which both hemorrhage and infection were absent or slight and in which, nevertheless, shock was observed. These facts of observation have led to the view that, beside hemorrhage and infection, there is an unknown factor at work.

Various views have been advanced to account for the nature and operation of this unknown factor. It was early suggested that serious wounds exhaust the nerve centers controlling the blood flow and that in consequence arterial pressure falls. This view has been extended so as to include the idea that the shocked man is suffering from general exhaustion not only of nerve cells, but of other parts of the body as well. Another view which has been widely noticed is that excessive respiration, by reducing the carbon dioxide content of the blood, causes such vascular changes as to reduce the volume of circulating blood. And still another suggestion is that the low pressure follows accumulation of fat either in the lungs or in the nerve centers governing the circulation; in the former instance the low pressure would be due to mechanical obstruction in the pulmonary capillaries, and in the latter case it would be due to injury of the vasoconstrictor center by anemia. None of these views as to the unknown factor in shock has been generally accepted. Possibly, as will be seen later, certain of them may at some stage have significance in the production of shock. The fact that the condition of shock has long remained unexplained, however, indi-

cated the need for further investigation. The question to be settled seemed to be a determination of what factor, naturally related to the onset of shock, may so operate in the body, when hemorrhage and infection are ruled out, as to induce the characteristic persistent low blood pressure of the shock state.

DUPLICATING IN EXPERIMENTS THE CONDITIONS SURROUNDING SHOCK

One of the fundamental principles of experimental research is that the phenomenon to be studied shall present, when experimentally reproduced, as much detailed similarity as possible to the phenomenon as it occurs naturally. This is a principle which has been largely neglected in experimental investigations of shock. There is no doubt that a persistent low blood pressure can be produced by a variety of means. Investigators have reported the duplication of certain aspects of shock by prolonged stimulation of nerves, by severe and long-continued manipulation of exposed intestines, by the application of acid to the abdominal viscera, by vigorous over-ventilation of the lungs, by repeated punching of the diaphragm, or by injecting into the circulation large amounts of cream. It is possible that such procedures induce changes similar to those which may occur naturally in shock; but no one can successfully argue that such procedures reproduce the circumstances which occasion shock after ordinary wounds or injury. Obviously, it is desirable to duplicate so far as possible the actual conditions which give rise to shock and then to analyze them to determine what factor among them is operative.

Shock occurs in warfare on an enormous scale. To find evidence of the interest which the subject of shock has aroused at times of fierce strife one needs only to look through any large catalogue of medical literature and observe the dates of publication of articles. In warfare the shock state occurs characteristically in association with extensive and severe wounds—wounds in which large tissue masses are shredded, torn or crushed; as, for example, when there has been rupture and mashing of muscle by shell fragments. Similarly in civil life, traumatic shock is seen characteristically after injuries under car wheels or in machinery, when limbs have been badly mangled.

As Cowell³ pointed out, there are certain very severe wounds in which death is certain to occur soon because of the anatomic damage which has been done. The patient's condition may be seriously complicated by abundant hemorrhage. In such cases, symptoms of shock are seen immediately; and from the earliest moment there is low pressure. This may be called "primary wound shock." On the other hand, there is testimony from a variety of sources⁴ that after large wounds the state of shock commonly does not appear at once, but develops in the course of a few hours. This is Cowell's "secondary wound shock." When shock thus develops it may be attended by little hemorrhage, and it may occur too soon to be due to infection. Since these facts have been actually observed by medical men and dressers working in front line relief stations, there is justification for looking for the development of a state of shock in which hemorrhage and infection are negligible factors.

EXPERIMENTAL PRODUCTION OF SHOCK

In order to duplicate in lower animals conditions which give rise to shock in man, the thigh muscles in the anesthetized cat were traumatized by means of a blunt wedge-shaped hammer. While being struck, the muscles were supported by an iron block. The trauma usually failed to break the skin, so that infection from without was impossible. Occasionally the femur was broken, but this had no important influence on the results which were seen. After this procedure the course of events was followed and the arterial pres-

Fig. 1.—Typical fall of arterial blood pressure after crushing of the muscles of the thigh: R , respiration; P , pulse.

sure was recorded by means of a mercury manometer. In Figure 1 is presented a record of the blood pressure changes typically seen after such trauma.

As Figure 1 indicates, the crushing of the muscles in the hind leg may have no immediate effect. After about twenty minutes, however, a fall of arterial pressure begins, and after about an hour the pressure has usually fallen to 80 or 90 mm. of mercury or even lower; that is, to a shock level. Pressure may persist at this level for several hours. Obviously, a general bodily condition resembling shock has been produced by duplication of circumstances which induce shock in man. The only variant from human conditions is the presence of anesthesia. That this is not a determining factor, however, is indicated by the use of a controllable anesthetic such as ether, which may be lightened as the animal goes into deeper and deeper stupor. The lessening of the ether concentration under these circumstances has no beneficial effect in improving the circulation.

THE PART PLAYED BY NERVOUS IMPULSES

The general bodily state which has been caused by the crushing of tissues in one hind leg naturally raises the question as to whether the widespread effect in the organism is due to nervous impulses roused by the trauma. These impulses on passing to the central nervous system might exert it as to produce profound depression or paralysis and the exhaustion which is apparent both in experimental animals and in human beings after trauma. Is that the case? The nature of the question permits the settlement of this question only by necessary to transect the spinal cord between the thoracic plexus or to sever all nerves of the region. It is to be injured in order to disconnect the region from the central nervous system. All this has been done and the denervated muscles

are traumatized, events occur similar to those seen after trauma with the nerves intact (Fig. 2). There is common testimony from men who have been seriously injured that the wounds are not painful; in other words, afferent impulses are not arriving from the injured region in any such intensity as to affect deeply the central nervous system. It would be rash, however, to argue that nervous impulses play no part in the establishment of shock; indeed, there are cases in which a pure nervous shock from trivial wounds seems to be present. From personal experience and from testimony of other observers, however, I am justified in reporting that these cases are rare. The vast majority of shock cases are associated with severe tissue damage. As shown in Figure 2, there is no essential relation between the production of shock in such instances and excessive stimulation of the central nervous system.

TOXIC MATERIAL PROCEEDING FROM WOUNDED TISSUES

If the general bodily state resulting from local trauma is not mainly the consequence of effects produced on the nervous system, the relation between the general and the local conditions may be looked for in the other great integrating system, namely, the circulatory. Quite possibly there is given off, from the injured tissue to the flowing blood or lymph, material which, when carried to the rest of the body, proves toxic and affects the vascular system in such a way as to lower arterial pressure. The idea can be readily tested. The blood vessels of the leg (the iliac artery and vein) are tied and the muscle then crushed. As stated above (Fig. 1), the arterial pressure usually begins to fall in the cat about twenty minutes after the injury. In Figure 3, the blood vessels of the leg were tied before the muscles were smashed, and ligatures were left in place for

Fig. 2.—Fall of blood pressure after muscle injury though the nerves to the injured limb had been cut. Rise of blood pressure to the original level after (A) crushing of the blood vessels to and from the injured region; B, left leg muscles hammered; C, right leg muscles hammered; D, clip on vessels to left leg.

thirty-three minutes after the injury. The record shows that there was no dropping of blood pressure during this period; but as soon as the blood flow was restored, the pressure promptly fell to a low level.

The fall of pressure after restoration of blood flow in the traumatized limb might be regarded as due to loss of blood and lymph into the damaged tissues and not to the washing out of toxic material from these tissues into the rest of the body. This suggestion was put to test by removing with symmetrical cuts the two hind legs and weighing them. The difference in weight, which in some instances was only 10 per cent. of the estimated blood volume, would not represent enough extravasated blood to account for the fall of pressure.

The conclusion appears justified, therefore, that a pressure-lowering substance passes from the traumatized region to the rest of the body by way of the circulation. Extravasation of blood may augment the depressant effect.

The conclusion just stated receives support from an experiment in which the muscle was injured, and while the pressure in consequence was falling, the vessels of the leg (the iliac artery and vein) were clipped. As shown in Figure 2, the occlusion of the vessels was followed by a progressive rise of pressure to the nor-

Fig. 3.—Failure of blood pressure to fall at the usual time after muscle injury if the blood vessels to the injured region have been tied. On restoration of the blood flow, the pressure promptly falls. *A*, vessels clamped; *B*, clamps off.

mal level. This evidence indicates, therefore, that whatever may be the substance arising from the injured tissues, it is fairly promptly changed in the body so that its effect is not permanent.

Experiments which have been performed by Cattell since returning to the United States indicate that the fall of blood pressure is not, at least in the early stages, associated with dilatation of the arterioles. This evidence is in agreement with that reported by Seelig and Lyon,⁵ by Mann,⁶ and also by Erlanger and Gasser.⁷ It is further testimony against the view that shock is primarily due to nervous exhaustion.

Careful examination was made of the lungs in several of these cases by Col. L. B. Wilson and by Major Henry W. Cattell, and in no instance was there evidence of any accumulation of fat. Furthermore, there was no twitching or other disturbance which might indicate that fat had passed through the pulmonary capillaries and into the central nervous system. The fall of pressure, therefore, cannot be attributed to fat embolism.

Although there was usually a change of respiration in the direction of greater rapidity and lessened amplitude, this was not such as to cause a washing out of carbon dioxide and a consequent acapnia. The lowered blood pressure, therefore, cannot be ascribed to such a change in the blood.

For a long time it has been known that tissue extracts, when injected into the blood stream, will cause a temporary fall of pressure. In 1903, Vincent and Sheen⁸ proved that watery extracts of a variety of tissues would produce this effect. Furthermore, Dale and Landlaw have shown that a characteristic shock-like condition can be induced by the injection of extremely minute amounts of histamin, a substance which Barger and Dale proved present in the mucosa

of the small intestine.⁹ The low pressure caused by this substance is not due to dilatation of the arterioles but apparently to dilatation of the capillaries with escape of plasma into the tissue spaces.¹⁰ This effect is in consonance with the evidence for diminished volume of circulating fluid and concentration of the corpuscles in capillaries in human cases. French surgeons with extensive experience in the war, Delbet¹¹ and Quénu,¹² have independently come to the conclusion that the phenomena of secondary shock are the consequence of absorption of proteolytic products arising from the region of the injury; and Turck¹³ has expressed similar ideas. There is the possibility that this *traumatic toxemia* may be closely related to "peptone" shock and that the toxic agent is, like "peptone," capable of making the capillary wall more permeable to the fluid portion of the blood. These suggestions must be regarded, however, as purely hypothetical. It is clear that a large field for investigation is opened by the facts above described.

A SECONDARY DAMAGE

Besides the primary fall of blood pressure induced by substances given off by the injured tissues, there is a secondary damage, which may result from the low blood pressure itself. As stated above, there commonly appears in clinical cases of shock a reduction of the alkali reserve of the blood, or an "acidosis" in the sense defined by J. L. Henderson. The reduction of the reserve corresponds roughly to the degree of lowering of blood pressure. In forty-four cases of shock and hemorrhage which I investigated at Bethune in 1917, the relations between blood pressure and the alkali reserve were as shown in the accompanying table.

When we consider that 50 per cent. by volume of carbon dioxide capacity is close to the boundary between normality and acidosis, it is obvious that the maintenance of a blood pressure above 80 mm. causes little

Fig. 4.—Record of an experiment showing the progressively harmful effects on the circulation of persistent low arterial pressure.

alteration in the blood, but that a reduction of the pressure below this level results in a marked diminution of the sodium bicarbonate as indicated by the carbon dioxide given off. These clinical observations have been confirmed by experiments. A cannula introduced through the chest wall and tied into the pericardium permits fluid to be introduced into the pericardial sac. By varying the pressure of this fluid, the output from the heart can be varied or held at any

pressure may be associated with constriction of the arterioles, in the late stages the arterioles may be relaxed because of such damage to the vasoconstrictor center that it no longer holds the vessels in tonic contraction.

TREATMENT OF SHOCK

The principles of the treatment of shock are suggested by a consideration of the facts and inferences outlined above.

In the first place, if a part of the body has become shattered and useless through injury so that it is impossible to save it, the harmful toxic effect of the torn tissue on the rest of the body may be avoided by applying tightly, as near as possible to the injured region, a tourniquet. Extreme care should be taken *not to remove the tourniquet before operating at a point proximal to it*. The reason for this urgency is that when tissues are deprived of their blood supply they undergo at a slower rate the same changes which they undergo when mechanically traumatized. During the course of military operations last year, several cases were reported of the sudden production of shock on removal of a tourniquet which had been applied to stop bleeding and left in place for an indefinite period. These observations obviously support the view of shock which has been outlined above. If a tourniquet used to stop bleeding is to be left in place for a long period, it should be applied at the most distal effective location. The surgeon must be guided in his decision to save or sacrifice the part by questions of viability, of gross infection in the excluded region, and of danger to the rest of the body from its retention. The danger of the tourniquet should lead, whenever possible, to the substitution of other methods of controlling hemorrhage. If the injured tissue can be removed promptly either by amputation or debridement, that should be done in preference to the application of a tourniquet.

Observations by Lieutenant Amb in the Surgical Research Laboratory of the American Expeditionary Forces at Dijon proved that there is a marked diminution of the heat production as the blood pressure is lowered. Furthermore, the man in shock sweats and thus loses heat both by evaporation and by greater conduction of heat through wet clothing, especially when he is exposed in cold weather. These considerations give a rational basis for the treatment of shock by warmth, a procedure universally recognized as of great value. Every effort should be made to avoid loss of heat from the shocked man or to restore heat that has already been lost. These objects may be attained by avoiding unnecessary exposure of the body and by use of hot drinks, warm water bottles, and proper blanket-ing.

The facts regarding the damaging effects of low arterial pressure which have been emphasized above should be emphasized again. If the pressure is allowed to remain below the critical level for a sufficient length of time, the vasoconstrictor center may be so profoundly affected that no measure will restore it to its normal condition. The transfusion of blood, for example, then results in only a temporary rise of arterial pressure, just such a rise as may be seen after total destruction of the center. As shown in Figure 4, the time element in the damaging effect of low pressure is of the utmost importance. If simple measures, such as warmth and fluids by mouth, do not in half an hour raise the pressure above the critical level of 80 or 90 mm. of mercury, the case should be treated as if it

were a case of hemorrhage; and the treatment should be prompt in order to avoid the progressive damage as time passes. There appears to be little doubt that the best method for raising the blood pressure is transfusion of properly matched blood; by such means not only is the pressure raised but oxygen carriers are added to the circulation. If blood is not available, Bayliss' gum salt solution,¹⁸ made of selected pure gum in physiologic sodium chlorid solution, or Erlanger and Gasser's² modification of this solution, may be employed. These colloidal solutions, if used early, can permanently raise arterial pressure. They do so by increasing the circulating volume of fluid. The corpuscles which are present are made to circulate more rapidly and thus to be employed more efficiently as oxygen carriers. There is no evidence that either the subcutaneous or intravenous injection of physiologic sodium chlorid solution has more than temporary value, if it has any beneficial effect at all.

SENSITIVENESS OF THE SHOCKED TO OPERATIVE PROCEDURES

In the earlier series of articles the sensitiveness of the shocked man to operative procedures was emphasized. Work done in cooperation with Lieutenant Cattell at the Surgical Research Laboratory at Dijon revealed the fact that not the operation but the etherization was the chief reason for the fall of pressure. If shock is already present in an animal, etherization until the wink reflex disappears may cause the pressure to fall 30 or 40 mm. of mercury (Fig. 4). On the other hand, the same degree of anesthesia may be induced by using nitrous oxid and oxygen in a ratio not exceeding 3:1 without any fall of blood pressure. There is little difficulty in bringing about satisfactory anesthesia or analgesia in shock cases with this ratio of the gases if there has been a previous dose of morphin. From suggestions which have been given above, it should be clear that morphin should not be given in such amount as greatly to retard respiration; and it should be clear also that at all stages deep anesthesia, or cyanosis or such rebreathing as would diminish the oxygen supply in the respired air, should be scrupulously avoided.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. CANNON AND BERNHEIM

DR. GEORGE W. CRILE, Cleveland: During the campaign of 1917 the various teams of the Lakeside Unit with the British and in later campaigns, did nearly 1,000 transfusions of blood, the results of which confirm Dr. Bernheim's conclusions. Surgeons must feel gratified that physiologists have undertaken the solution of certain urgent practical problems. Dr. Cannon and many of his colleagues did most valuable work during the war. There are three practical reasons why we are unable to accept Dr. Cannon's work as conclusive: 1. Patients with extensive wounds of the extremities to which tourniquets had been applied so that the blood supply of the injured part was so completely blocked that no tissue poisons could have been introduced into the circulation, have passed into shock and have died from shock. Patients have died during operations from shock in which a tourniquet has completely controlled the circulation of the blood of the injured part. The tourniquet does not block nerve impulses; it does block circulation. 2. Nerve blocking does prevent shock. It is possible to kill animals by traumatizing nerve tissues without touching any other tissue. Indeed, if Cannon believes that the nervous system bears no part in shock, it would be

18. Bayliss: Intravenous Injections in Wound Shock, London, 1913.

an unfortunate conclusion from the surgical point of view. In this the work of men like Cabot, with low spinal anesthesia, is most illuminating. Cabot performed 180 amputations of the thigh—ninety under ether anesthesia in the usual way, ninety with low spinal anesthesia. The death rate of the latter series exactly reverses the death rate in the former series, that is, under ether anesthesia without blocking the spinal cord there were two deaths out of three; with the blocking of the spinal cord there was one death out of three. Nitrous oxid is almost a specific preventive of shock. This action of nitrous oxid in the presence of toxins and proteins has been demonstrated conclusively in my laboratory as appearing from its influence on the nervous system. As a matter of fact, I believe that we must cling to the principle that a number of factors are concerned in the causation of shock. Of these various causative factors, Cannon's is one and in practical surgery one of the least important.

DR. OSWALD H. ROBERTSON, New York: While it is generally agreed that in cases of severe hemorrhagic transfusion is the most effective method of treatment, I do not think that gum acacia solution, or gum saline as it is called, should be dismissed as having little value in this condition. The reports on the use of gum acacia solution in hemorrhage vary considerably. Some people are very enthusiastic, others say it has little or no effect. I think this diversity of opinion is due to several factors. I had an opportunity during the course of the war to investigate the subject in a number of our hospitals. Certain men reported very favorably from the clinical side; they got excellent results. Others are inclined to regard it as being the last resort if they could not get blood. It seems to me that the reason for this is that people, on the whole, are expecting gum acacia solution to act as a "cure-all." There were four classes of cases in which gum acacia solution was of very little use. In the first place, cases of shock or hemorrhage which had been in this condition for twenty-four to forty-eight hours responded very little to gum acacia, or to an injection of any substance, even blood. These patients had been in a condition of oxygen starvation so long that nothing would benefit them. Without morphin and rest any intravenous treatment is harmful if given before the patient has begun to recuperate. Third, in the case of those patients who had lost large quantities of blood, and who were very anemic, gum acacia solution increased the volume, the blood pressure rose temporarily, and then it dropped. What the patient needed was new blood. He did not get it, therefore, he died. In the fourth class, the patient often had a concealed gas gangrene and in these cases gum acacia solution was of no avail. Where gum acacia solution was used intelligently and with these considerations in view it had a very definite value and was successful in many instances. From intensive study of hemorrhage in the war we have learned the value of forced fluids in the treatment of hemorrhage. It is well known that considerable fluid is contained in the body tissues outside of the circulation. After hemorrhage this fluid is poured into the circulation in an attempt to make up the lost blood volume. If the hemorrhage has not been very severe sufficient fluid can be supplied by the tissues to make up for the lost volume and the pressure comes back to normal. If the hemorrhage is very severe the body tissues cannot supply sufficient fluid to make up the volume and outside assistance is needed. Even with moderate hemorrhage if the fluid reserves are low, before these can be made up fresh fluid must be given by forced fluids through the digestive tract. So that very soon the volume begins to rise and with it the blood pressure. Fluid may be given in very large quantities by mouth, as much as a liter, and by rectum. It is absorbed rapidly. In severe cases transfusion is needed. Forced fluids should be considered an essential part of the treatment of hemorrhage in all instances. Even in cases of severe hemorrhage transfusion makes up only a small part of the loss, the rest must be made up from the fluid of the tissues.

DR. HOWARD T. KARSNER, Cleveland: So far as the general proposition of the success of transfusion in cases of hemorrhage is concerned, I can support everything Dr. Bernheim said. From the point of view of a laboratory man, however, numerous points are to be considered and I feel

that some exception must be taken to the statement of Dr. Bernheim that the citrate method has proved itself to be the best method of transfusion. Certain methods have been tried with certain degrees of success. I have been particularly impressed by a paper by Lindemann on the transfusion by the needle syringe method in which the blood is transferred from one individual to another almost directly, with a minimum of contact with foreign surfaces. It is unqualifiedly true that the longer the blood stays out of the body the more likely a change in the course of transfer. The more immediately the blood is changed from donor to recipient the better the results are likely to be. Of course, I am not taking into account the amount of blood transferred. The addition of chemicals, however, places in the blood a factor which otherwise would not have to be considered. It adds a variable and a considerable number of variants. As regards anaphylaxis and anaphylactic symptoms, I have seen nothing which would indicate that anaphylaxis plays any part in regard to transfusion. In the matching of blood we have a problem which affects the individual patient. I would like to put myself on record as favoring the grouping of donors and of patients. I am convinced that the safest method of matching donor and recipient is to have them in the same group. This matter has been the subject of investigation in my laboratory for the last year, with the collaboration of Dr. Reckert. The principle of serum for testing blood for transfusion is unsatisfactory if we are to preserve this serum for any length of time. After the lapse of five or six weeks the serum not only lost its potency but also its specificity. The final comment is on the matter of simply matching up the recipient's serum against the donor's corpuscles, maintaining that if in a test tube or slide it does not agglutinate the transfusion is safe. I believe in testing blood and in order to make this test the serum must be preserved in some other way than by drying.

DR. R. PICQUÉ, Bordeaux, France: During the last year of the war we experimented with thirty-six cases of blood transfusion; thirty-two were cases of hemorrhagic shock, with twenty-one successes; four were cases of operative shock, with two successes. As guides for transfusions we utilized, first, clinical examination of the patient, and second, the blood count. In two thirds of the cases the scale as per Depage and Govaert (de la Panne) was proved correct. But in one third of the cases, when seen near the lines, we noted that in the recently wounded (first to sixth hour), though the men were almost bloodless from severe hemorrhage of a most serious type, the leukocytes were almost normal in number. Third, the blood pressure is a guide. The instrument of Pachon (of Bordeaux), which is ultrasensitive, allows us to follow the blood pressure from hour to hour and to seize the moment when loss from hemorrhage indicates instant transfusion. In such cases, either we transfuse first then operate; or we operate first and transfuse afterward. Either immediately after the venous injection, or later when serotherapy has proved unable to sustain the blood pressure, and at all times in order not to waste blood we only practice transfusion on those whom we judge able by a radical operation to protect from infection for transfusion itself has not a single action against infection. As to results, in these picked cases we have obtained, first, twenty-one "resurrections" among simple, severe hemorrhages. Second, two successes among serious cases of operative shock, where serotherapy had proved absolutely impotent. The wounded are constantly watched and studied in well warmed rooms, either in the divisional ambulance or the subterranean surgical stations. The study of the cases is made by trained, experienced surgeons or nurses. The blood pressure instrument permits the surgeon to keep in instant touch with the patient's condition before and after transfusion. Those giving blood for the transfusion are the surgeons, dressers, nurses of the ambulance who after administering 500 to 800 grams of their blood still continue to work at the bedside of the wounded. We have not studied the agglutination and we have not observed any bad effects among our cases, except for two cases of hemoglobinuria, with serious results. We could use use of the ampule of Kimplon and the citrate method of Jonde.

DR. RICHARD LEWISOHN, New York: It is a great gratification to me that the sodium citrate method, which I first suggested in January, 1915, was adopted officially by the American Expeditionary Forces. The safety of the method is based on the atoxicity of the dose. The dose of sodium citrate is so small that it will not produce any toxic symptoms. Another important factor is that sodium citrate, though it prevents coagulation of the blood outside of the body, shortens the coagulation time temporarily when introduced into the body. This shortening is one of brief duration and the blood coagulation time falls back to pretransfusion time in about twenty-four hours. The advantages of the method are its simplicity, its flexibility, the possibility of the transfer of blood from one place to another, the very important factor that donor and recipient do not have to be together in the same room and do not have to be attached to each other by some form of apparatus, and that this transfusing can by simplicity of technic be repeated as frequently as we want to do it. The disadvantage of the method is the occurrence of chills. Chills occur in about 20 per cent. of the cases. The syringe methods and the Unger apparatus usually cause chills in 5 to 10 per cent. of the cases, so that the disadvantage is really not very great. A few points in the technic are very important, the proper insertion of the cannula into the vein and the use of very large cannulas for the donor so that the blood runs out very rapidly. My personal experience comprises about 300 cases. I have never seen any bad results. In another field of blood transfusion we have to make improvement and that is in cases of sepsis. This improvement will lie in the rapid immunization of the donor. At present it takes from two to three days to immunize the donor for a septic patient. If we can do this in a few hours, another field for transfusion will be opened up for us.

DR. WALTER B. CANNON, Boston: Dr. Bernheim suggested that efforts should have been made in France to assure transfusion of blood rather than injection of gum-salt solution. The resuscitation teams in the A. E. F. received about sixteen hours of instruction; about one hour was spent in considering gum-salt solution, and most of the rest of the time was spent in practicing blood transfusion. As long ago as last July we urged that gassed men be placed near the shock ward to provide blood for shock cases. And when later the badly wounded were found segregated, with the result that there was no possibility of getting blood for them, we called attention to the handicap they thus suffered, and again urged putting lightly wounded men near them to supply blood for transfusion.

Dr. Crile mentions lack of agreement regarding the toxic origin of shock. Possibly there is more agreement than he realizes. In the last report of the English Medical Research Committee on Shock, surgical, biochemical, physiologic and pathologic judgments all came to the support of "traumatic toxemia" as a highly important factor in the causation of shock. Furthermore, when the facts reported above were presented last October before the Société de biologie in Paris, Delbet, the well-known French surgeon, remarked that the meeting would be historic because biologists, physiologists and surgeons had for the first time agreed on the toxic origin of shock. Dr. Crile has argued that shock is of nervous origin because he has seen alterations in nerve cells in tissues taken from shocked animals. These alterations may be present in nerve cells, but one may disagree with Dr. Crile's interpretation of them. Doley, the cytologist who worked with Dr. Crile, admitted that the same cellular alterations seen after shock are produced by hemorrhage. But the low blood pressure of shock is equivalent to hemorrhage. The changes in nerve cells taken from the shocked animal may be interpreted, therefore, not as the cause, but as the result of shock. As to the practical bearings of our views, Dr. Crile and I agree in being disturbed about the same thing, that is, rough surgery. He is fearful lest rough surgery affect nervous tissue, and I am fearful lest it may affect all tissues, including nervous. I do not wish to detract in the slightest from the moral effect of Dr. Crile's teachings; I would only insist that surgeons must not unnecessarily injure any tissues.

DR. BERTRAM M. BERNHEIM, Baltimore: Dr. Crile is interested in the nerve and Dr. Cannon in tissue; both are interested in surgery, and I am interested to see that they do not have any loss of blood. So that if we all get together by mixing a little blood with the tissue and nerves it will be all right. During the war we must consider the greatest good to the greatest number. Any man who maintains that the Kimpton-Brown method or the Pederson method is one twentieth as good as the citrate method has not been in France. I was rather surprised to hear Dr. Robertson make excuses for gum acacia solution. The advocates of gum acacia solution are always making excuses for it. That in itself should rule it out. They are always accusing the other fellow of not using it right. I have never found a man who had any good to say of it. There are men in this audience whose experience with it proved disastrous. Certain men here have seen deaths from it. I not only did not help, it killed men. While I was in France I did not transfusion. My sole object in reading this paper was to show that substitutes for blood are not of any help, and that we have a method of doing transfusion which any one can use. What I want to insist on is that the laboratory men find a method of preserving blood so that you can go to a corner drugstore and get half a liter just as you can anything else.

SCIENTIFIC MEDICINE—YESTERDAY AND TOMORROW*

GRAHAM LUSK

NEW YORK

Last winter I heard a talk by Galsworthy at the University Club in New York. His strain was that men who had fought in the war had become mentally addicted to the contemplation of their own past and that they could not look forward with hope or enthusiasm to the future. It seemed utter nonsense; and yet this theme has been so stressed that it has affected seemingly well balanced men. Only last Sunday a little girl visiting her grandfather told him that her mother was spending the morning studying pathology, while her father, home from France three months, was occupied in chasing butterflies. The young men of this country cannot become addicts of the pastime of butterfly chasing when the advance of the world is so largely in their hands.

The fathers of men now living, fathers who had been engaged in desperate fighting for four long years of civil war, returned after the war to their former occupations, some of them following medicine with joy and in careers of distinction. Galsworthy thoughtlessly disparaged the character of that war, the battles of which were much costlier in human life than those of the Franco-Prussian war of 1870, and a war in which one man out of every four living in the Confederate States was under arms; as large a proportion as served in Great Britain during the recent conflict. Do we, who are most of us the descendants of this race, propose to chase butterflies when the opportunity for carrying on the treasured learning of the world and for its future development is placed fairly and squarely on our shoulders? The meeting held today answers this in the negative.

Twenty years ago (June 16, 1899) Theodore Jane-way, then 27 years old, wrote me that he would give up an idea he had had of going to New Haven to teach pharmacology at the Yale Medical School, and that he would conduct an "elementary clinic" for the benefit

*An address delivered before the American Society for Clinical Investigation.

of second year medical students. I think it is a lot of interest to read the letter:

Your letter came to me at a most opportune moment. I had been going over the points of our discussion and agreeing with myself both pro and con, and the more I thought the more everything seemed to point to the folly of giving up what really most appeals to me in medicine, and opportunities which could hardly come again, for an exchange. It seemed more and more possible that I might much more nearly accomplish what I want to in my life where I am and where everything seems open to me.

Then came your most encouraging words, which made probabilities of possibilities and made me feel that if you were working for such ends in New York and had such ideas, that Bellevue could be made a sort of which should take some part in the advance of true medicine and know ledge and not merely diffuse what is already known. I appreciate your letter highly and I want to thank you very much for it.

I have told Dr. Biges that I will do all of the elementary clinic next year that they will give me and I will do my best to make it carry out the ideas that you and Dr. Dunham have, so far as they seem capable of translating into actual cases available. I am reading, I feel now and I feel much that is suggestive, though of course I can do but the reverse of what one would pursue in instruction from the concrete case. It is nice reading, and his reason is more true from the desire to prove more than the facts warrant.

I trust it will be possible for me to keep in touch with your work and Dr. Dunham's next winter and especially with your enthusiasm, and that I may be able to persuade the students to regard symptomatology as the physiology of the "sick life." It will certainly be a most interesting experiment from my side.

This letter gives no picture of New York medicine as it was then. One should remember that Meltzer, at the time, was a practicing physician, snatching such moments of rapture as were his when he drove down Fifty-Ninth Street, tied his horse to a lamp post near the P. and S. and, with his coachman who acted also as laboratory servant, entered the dingy recesses of that college and ascended to the laboratory of physiology, there to perform some fundamental experiment, perhaps one on the nature of shock, for example. At that time Hertzer had just undergone metamorphosis from a specialist in nervous diseases into a physiologic chemist. Park had established a modern laboratory in the board of health. But besides this there was little to encourage the adventurer into clinical science. As matters of fact he it recorded that a few years later the medical faculty to which Janeway was attached refused him a teaching position in Bellevue Hospital, though the salary belonging to the position had been raised from outside sources, and the same faculty held a solemn, special meeting to discipline me because I had spoken before the students expressed opinions favorable to the Johns Hopkins Medical School. These were days when there appeared to be no future for clinical science, days in which there was almost no scientific or social or financial influence making for its advance. And yet even in this country, since that time, have we lagged out backward in this direction, not on account of the influence of any special men, but because there has been no primary mission of a medical school to take any part in the advance of true medicine. It has been merely to diffuse what is already known, and that is not really right. This society bears witness to the situation and will never forswear its friendship to the medical fatherlies.

It is no wonder that German medical science will not follow the lead of France after 1870;

but there are indications that such a fate awaits it. It has been reported from Munich that immediately after the armistice a society for the conservation of German intellectual interests was formed, Friedrich von Müller, Germany's greatest professor of clinical medicine, representing medicine. A month later it was reported that an academic meeting held Dec. 16, 1918, was broken up by representatives of soldiers and sailors who, armed with guns, revolvers and hand grenades, entered the hall in which the meeting was taking place. The *Münchener medizinische Wochenschrift* describes this under the caption "Die Herrschaft des Terrors" (The Reign of Terror) and states that the presence of mind of those composing the gathering alone prevented disastrous consequences.

About 1890, referring to the prevailing vogue of General Boulanger in Paris, Carl Voit said to me that unhappy political conditions acted as a depressant on a wonderfully gifted people. One can easily imagine that a similar depression will fall on Germany. Even before the war, German science had shown signs of decay. I remember traveling up the Rhine with a distinguished Austrian professor after we had attended the last international physiologic congress held at Groningen in 1913. He said to me:

The best papers read at the congress were by English and Americans. The best thing shown there was Abel's artificial kidney. You heard that disgraceful row between Rohmann and Abderhalden. Just because Abderhalden had gained a little fame, Rohmann was determined to pull him down. The Americans and the English would not have behaved that way. It is because the Germans are not "gentlemen," as you English speaking people say.

Alas, in such a comparatively superficial attribute as bad manners one may perhaps find the interpretative symbol of the cause of the war. I have heard it queried whether the bad manners of political and military leaders of the German people were not the primary curse that brought the world near to the brink of hell.

There were many of us who formerly believed that German appreciation of our scientific work meant that such work was good. The incentive to this attitude has passed. But we may look in compensation for an appreciation by British men of science which, in keeping with British character, will not be outspoken but which nevertheless will be keenly attentive to the better class of work that we may do. I have heard it stated that, while the French are brilliant and the Germans thorough, the British are both. If you look back into their history for three hundred years there is no hiatus in their production of distinguished, creative, scientific minds. Those who doubt this statement should read the impressive "General Physiology" of Bayliss. We may also expect much from a reawakened France.

But above all we must learn to appreciate honest, careful work done by those who live around us, learn not to steal another man's ideas, and learn also how to bear adverse personal criticism.

A few days ago I was chosen arbiter in a dispute between some New York and Boston people. I said to the parties concerned that their discord and criticism of each other had led to the accomplishment of much better work than if all had been harmonious; and, though at first they were somewhat surprised at the statement, they freely admitted its truth.

I once visited Pilgner at the time when he was engaged in a vitriolic polemic arrangement of Voit. A

few days later in Munich I told Voit that I had called on Pilgrger.

"But he did not receive you?" "Yes."

"But he did not know whose pupil you were?" "Yes."

"So, Sie sind in dem Löwenkäfig gewesen!" (So you have been in the lion's cage!)

I remarked that in conversation Pilgrger was willing to grant the possibility of the production of sugar from protein to which Voit smilingly replied:

"Ja; der Löwe wird bald zahm." (Yes; the lion will soon become tame.)

There is no doubt that irritating criticism is a highly beneficial stimulus. Only the vain refuse to hear it; and the teachings of such become dogmatic, their investigations futile.

We Americans have learned much from England, France, Italy and Germany. We have brought over the seas their knowledge and have set it up here as a common heritage. Sometimes we have advanced beyond their methods, and at other times have fallen far short. We have just helped to rescue Europe from torment. In comparison with ourselves they are living in abject poverty, and we are selling to them the necessities of life, wheat and cotton, at prices which are highly profitable to our people. They are under great financial strain in the struggle for existence, and will be so for many years. In this great land of ours, which is overflowing with opportunity and abundance, it is of very especial importance to elevate our intellectual standards. Many scientific men hardly seem to realize the heavy world responsibilities which have been placed on us.

Money alone will not produce a creative mind; money may well spoil such a mind. The best work does not always come from the most richly endowed institutions, nor from those laboratories that have the largest number of assistants and laboratory servants. It is the spirit that matters. This spirit cannot be manufactured according to a formula. It belongs to the genius of the people. The spirit animating this society gives it the power to achieve greatly in the advancement of American medicine. This spirit is the greatest present asset of American medicine.

The members of this society, urged on by the vision of the condition of the world, have the honorable privilege to render high service for the benefit of all mankind, perhaps winning through scientific achievement the medical leadership of the world.

477 First Avenue.

Japanese Opium Trade with China—In an article which appeared in the *North China Daily News*, Dec. 17, 1918, it is stated that the trade in morphine is still flourishing. As morphine cannot, however, be purchased in Europe, the seat of industry has been transferred to Japan, where the Japanese are now manufacturing morphine. Wholesale contraband traffic between Japan and China is carried on. It is conservatively estimated that during the last year 18 tons of morphine were imported by the Japanese into China, and the amount is said to be steadily increasing.

TYPE I PNEUMOCOCCUS LOBAR PNEUMONIA AMONG PORTO RICAN LABORERS

AT CAMP JACKSON, SOUTH CAROLINA

JAMES H. PARK, JR., M.D. (CHICAGO, ILL.)
First Lieutenant, M. C., U. S. Army

AND

H. T. CHICKERING, M.D. (NEW YORK)

Captain, M. C., U. S. Army

CAMP JACKSON, COLUMBIA, S. C.

Shortly after the epidemic of acute respiratory disease appeared at Camp Jackson in September, 1918, 1,653 Porto Rican laborers arrived in camp direct from

Effect of serum in a case of Type I pneumonia of the right lung. (Left) was 103.5°; (middle) 110; (right) 100. B. C., blood cultures negative.

Porto Rico to be employed in the construction work incident to the enlarging of the cantonment.

A large proportion of these men were poorly developed individuals, most of whom suffered from chronic hookworm infection as well as from other intestinal parasites. They appeared markedly undernourished, with their Palm Beach suits and Panama hats, for the almost freezing nights of South Carolina in November and December.

Soon after the arrival of these Porto Rican laborers, respiratory infections developed among them, and 1,000 were admitted to the base hospital with the diagnosis of influenza. Of these, 220 exhibited signs of complicating pneumonia, and sixty-seven died, a mortality of 30.4 per cent.

During the height of the epidemic, it became impossible to take cultures of the sputum of all individuals

having pneumonia, but as soon as the hospital assumed approximately its normal condition, the careful examination of the sputum of all cases exhibiting pulmonary lesions was again resumed.¹

During the early part of the influenza epidemic among the Porto Ricans, atypical types of pneumonia were seen; but later, beginning about Dec. 15, 1918, a number of patients were admitted who exhibited the more usual signs of lobar pneumonia.

In the early part of the summer, in May and June, twenty-two of fifty-one cases of pneumonia were Type I pneumococcus infections. From that time on until Sept. 15, 1918, only twelve more cases of Type I pneumococcus infection occurred out of 122 cases of pneumonia. While the statistics covering sputum and blood culture examinations during the influenza epidemic are extremely fragmentary, apparently there were but few Type I pneumococcus infections of the lung, as but three patients were found to be harboring that type of pneumococcus in the sputum, and only two patients were shown to have positive blood cultures, as shown in Table 1.

TABLE 1.—FREQUENCY OF OCCURRENCE OF TYPES OF PNEUMOCOCCI INFECTIONS

Sputum Cultures:	No.	Blood Cultures:	No.
Pneumococcus Type I.....	9	Pneumococcus Type I.....	2
Pneumococcus Type II.....	47	Pneumococcus Type II.....	17
Pneumococcus Type III.....	29	Pneumococcus Type III.....	9
Pneumococcus Type IV.....	194	Pneumococcus Type IV.....	16
Staphylococcus aureus.....	18	Staphylococcus aureus.....	1
S. influenzae.....	13	S. hemolyticus.....	2
S. hemolyticus.....	8		

Type I pneumococcus infections of the lung occurred but rarely among the soldiers of Camp Jackson during the epidemic, as compared with other types of pneumococci and other organisms. Of 312 postmortem lung cultures, this group of organisms was encountered only eight times, whereas other types of pneumococci were found 131 times and *Staphylococcus aureus* 153 times.² It seemed to be a matter of some interest, therefore, that among the respiratory infections affect-

1. The sputum examinations were all made in a separate room, the so-called "pneumonia" room, specially fitted and equipped, Miss Fric Davidson and Private R. A. Ambler, under the supervision of Capt. H. T. Chickering and Lieut. J. H. Park, Jr. As soon as a patient arrived in the pneumonia ward, notice of his arrival was sent to the laboratory, and the specimen was collected by Private W. J. Archer, who was instructed concerning the importance of obtaining sputum from the deeper air passages.

2. Chickering, H. T., and Park, J. H., Jr.: *Staphylococcus Aureus Pneumonia*, J. A. M. A. 72: 617-626 (March 1) 1919.

ing a group of Porto Rican laborers, the incidence of Type I pneumococcus infection should be much greater than among the soldiers in camp.

Table 2 shows the incidence of the various types of pneumococcus among the white and black soldiers, and among the Porto Ricans, over a period from Dec. 15, 1918, to Feb. 1, 1919.

TABLE 2.—INCIDENCE OF VARIOUS TYPES OF PNEUMOCOCCI

Type	White	Black	Porto Rican
Pneumococcus I.....	1	2	24
Pneumococcus II.....	4	2	0
Pneumococcus III.....	4	0	2
Pneumococcus IV.....	97	17	16

The Porto Rican laborers lived under crowded conditions in wooden buildings. Fourteen barracks were used, 120 feet long by 20 feet wide. The bunks were arranged in two tiers, the lower being about 3 feet from the floor. In this way, from 120 to 160 men were accommodated in each building. The five kitchens, formerly occupied by the depot brigade, were used as mess halls. On account of the cold, the screens were removed and the openings boarded up. The latrines were about 200 yards from the barracks. Under these conditions there was abundant opportunity for close contact and wide temperature variations.

The first Type I infection among the Porto Ricans was discovered by a routine lung puncture made post-mortem. This patient, for some unexplained reason, had not been transferred to the pneumonia ward, and no sputum examinations had been made. From that time on all cases of pneumonia among the Porto Ricans, as well as among the soldiers, were treated in wards especially designed for pneumonia, and cultures were made with as much dispatch as possible.

The sputum was cultivated by streaking directly on blood agar plates, by mouse inoculations, and by the use of the Avery 1 per cent. glucose blood broth. The results of sputum cultures were checked up by repeated blood cultures and by cultures made from exploratory puncture of the lung when indicated.

The patients in whom evidence of Type I pneumococcus infection were found were treated intravenously with antipneumococcus serum according to the method described by Cole.³

* No evidence of malaria was found in any of the cases. When there were complications, these are stated in the last column.

+ Right lower and middle.

+ + Means positive for Type I pneumococcus.

§ Positive for Type I pneumococcus and Bacillus influenzae. Refers to organisms recovered from the nose.

As will be seen in Table 3, these Type I pneumococcus infections among the Porto Ricans resembled more nearly the kind of pneumonia ordinarily encountered in practice, rather than the type of pneumonia experienced as a complication of the recent epidemic of respiratory infection. When a history could be obtained, the onset, in most instances, was found to have been sudden. The type of involvement was, clinically, lobar in twenty-seven, or 81.8 per cent., out of the thirty-three cases studied. All but two cases, moreover, showed the presence of some degree of leukocytosis. In eight cases, or 24.2 per cent., there was a positive blood culture. Thirty-one patients were treated with serum. One case was discovered only postmortem; the other two patients were out of danger when the type of infection was determined.

The smallest amount of serum given to any one individual was 85 c.c.; the largest, 1,050 c.c., with recovery. The average amount of serum administered was 375.8 c.c.

The serum therapy of pneumonia in the case of white persons is followed by serum sickness in a large percentage of cases—probably around 80 per cent.—anywhere from the fifth or sixth day to the second or third week after the administration of the serum, usually about the tenth day.

It was noted during the summer that the occurrence of serum sickness was much less among the negroes, who had been treated with immune horse serum, than among the whites. The absence of serum sickness was even more striking among the Porto Ricans. Only four of the thirty-one men treated showed evidence of serum sickness, as urticaria, muscular and joint pains, headache or fever.

The results of the serum therapy were very satisfactory; only two patients died in this series of thirty-three. One patient died suddenly on the eighteenth day during convalescence, apparently from a pulmonary embolus. No necropsy was granted. The second developed an empyema, and subsequently a severe facial erysipelas with which he died a few days later, on the twentieth day of the disease. The therapeutic results are especially gratifying, as a majority of these men were in wretched physical condition. Sixteen, at least, were shown to be harboring the hookworm in the intestine. Eight of the thirty-three had a pneumococcus bacteremia, which may be taken in general as evidence of severe infection.

Of the complications, four patients developed empyema, and three recovered after thoracotomy and drainage. Four developed otitis media and one of these an acute infection of the mastoid cells which necessitated a radical operation. Several had skin abscesses, one a phlebitis, one a submaxillary adenitis, one acute catarrhal appendicitis, and one an epididymitis. Two had complicating facial erysipelas.

During the same period there were three other cases of Type I pneumococcus infection among the soldiers. One of the patients was white, and two were colored. They were treated with serum and recovered.

SUMMARY

Porto Ricans under favorable conditions are susceptible to lung infection by the Type I pneumococcus. The disease pursues a typical course, accompanied by a bacteremia in about the same proportion as among white persons.

Specific serum therapy seemed to influence the disease. The mortality of this series was 6 per cent.

The incidence of serum sickness following the administration of antipneumococcus immune horse serum was infrequent as compared with our usual experience among white persons.

END-RESULTS OF ARTERIAL RESTITUTION WITH DEVITALIZED TISSUE

C. C. GUTHRIE, PH.D., M.D.

Professor of Physiology, University of Pittsburgh School of Medicine
PITTSBURGH

Jan. 22, 1908, the right common carotid artery of a young, adult, female dog was divided, and a segment of vena cava, preserved for sixty days in formaldehyd solution, was interposed and sutured to the ends of the artery. The implanted tissue was treated with ammonia and absolute alcohol, and was impregnated with petrolatum, just prior to the operation. Feb. 12, 1908, the artery at the site of the operation was exposed, and a direct examination revealed an active circulation through the segment.¹

The animal was demonstrated before the St. Louis Medical Society, Feb. 29, 1908, at which time, as far as could be determined by palpation, pulsation in the common carotid arteries was the same on the two sides.

Clinical examination, from time to time, demonstrated like pulsations in the two common carotid arteries. On the right side, at the site of operation, a dense nodular structure could be felt on the course of the artery. The animal raised pups in 1909-1910, and whelped several times in immediately succeeding years, but failed to raise litters. She remained in excellent condition except after occasional fights with other dogs, until age led to a general physical decline. For about six months prior to death, the decline grew increasingly more marked, and for several weeks preceding death she showed great physical weakness, with loss of appetite; emaciation became correspondingly evident. Two days before death she was barely able to rise to her feet, and was unable to stand for more than a minute. An examination revealed the pulse in both common carotid arteries to be the same by palpation. The animal died suddenly, March 20, 1919, just after the attendant gave water. According to his statement, she fell over dead—there was no struggling.

An examination shortly after death revealed the two scars of the previous operations: the first, for the operation proper, Jan. 22, 1908, and the second, for exposing the structures for direct examination, Feb. 12, 1908.

There was an enlargement of the right common carotid artery about 3.5 cm. long and 2 cm. in diameter on the course of the artery near the root of the neck, several centimeters distal to the origin of the artery. Above and below, the artery appeared and felt normal. The enlargement was fibrous and vascularized on the surface, and to the touch was resistant, but springy and apparently hollow.

A connection through the mass between the two parts of the artery on each side was demonstrated by manipulation under liquid, and confirmed by section.

COMMENT

This experiment was undertaken in an attempt to obtain conclusive evidence as to whether devitalized tissue may serve adequately and indefinitely to transmit blood in vascular restitution. At that time, others

were advancing the view that implanted vascular tissues resumed active, vital functions, even when the tissues employed had been removed for considerable periods from the body, or when their source was of a species different from the host. Our results from implanting vascular segments of cat and rabbit into dog, namely, effecting a restoration of good mechanical function, notwithstanding profound degenerative changes, had led me to suspect strongly that mechanical function in itself was not evidence of tissue survival; and I had expressed the view that, to restore and maintain mechanical function, such an implanted segment need only temporarily restore mechanical continuity and serve as a scaffolding or bridge for the laying down of an ingrowth of tissue derived from the host. For this reason, the implanted tissue was subjected to treatment that would, beyond question, assure its complete devitalization. Others have abundantly confirmed the findings, the most recent work being that of Nageotte and Sencert.²

An interesting feature of the experiment reported is that it is the first of the kind, as well as the longest in respect to end-results.

It is planned to report the results in detail elsewhere in collaboration with Prof. Oskar Klotz, to whom my thanks are due for the necroscopic examination, for preparing and preserving the gross specimen, and for conducting the microscopic study of the tissues.

TREATMENT OF GUNSHOT WOUNDS OF THE ABDOMEN*

JOHN H. GIBBON, MD.

Colonel, M. C., U. S. Army

PHILADELPHIA

In the treatment of gunshot wounds generally, the last five years have witnessed great change and great improvement. In the treatment of gunshot wounds of the chest and of joints the advance has been most striking and will greatly change the civil practice in these fields; but in abdominal surgery it cannot be said that any wonderful change or improvement has been made. Because of the great prevalence of shell wounds over those made by high velocity bullets, operation in these cases has been much more regularly resorted to than, for instance, at the end of the Boer War. During that war it was undoubtedly true that patients did recover after penetrating and perforating wounds of the abdomen; but I cannot say that I saw in nineteen months spent in advanced and base hospitals a single instance of this kind.

In a communication of this length it is impossible to go deeply into the literature of the subject or to give extensive tables of statistics, even if this were desirable, and I shall confine myself to personal experience and observation.

NEEDLESS ABDOMINAL EXPLORATION

One of the most important things in the treatment of gunshot wounds of the abdomen is the ability to estimate fairly accurately whether the missile has really penetrated the abdominal cavity, and if so what struc-

tures have probably been damaged. This may not at first thought appear to be of the prime importance that it is, for one may say it is safer to open the abdomen in any case and determine whether penetration has occurred and what viscera, if any, have been injured. But, taking a large number of cases, this is not true; for one would find himself doing an exploratory laparotomy many times when there was no penetration; when the injured viscus, such as the liver, were better undisturbed; when the injury was above and not below the diaphragm, and in many cases in which the patient had multiple wounds and the prolonged negative exploration only added to the risk of life.

If a man has, for instance, a compound fracture of the leg or thigh, and perhaps a number of wounds of less severity, one should be very sure that a wound which would seem to have involved the abdomen really entered it before subjecting the patient to a deliberate abdominal section and a prolonged search for injury of the viscera; the other wounds alone render this case a serious one, and their treatment must require considerable time and involve a prolonged anesthesia. I do not mean, of course, to say that the abdominal wounds are not the most serious, or that they do not demand first consideration; but I would suggest that here, as in civil practice, one has no right to subject a patient to a needless abdominal exploration, especially when care and the exercise of judgment may show that such an operation is unnecessary. Numerous instances illustrating these points must come to the minds of many, and a common observation has been that many wounds which would certainly seem to have involved the abdomen were only wounds of its wall, and that others, which were small and seemed trivial at first sight did involve the abdominal viscera.

VARIOUS TYPES OF WOUNDS

A common type of wound of the wall which produced shock and abdominal rigidity was that caused by a shell fragment and characterized by a large ragged wound of entrance, probably by a larger one of exit, by extensive ecchymosis, by marked abdominal rigidity, and by costal breathing. In such cases the wound should be excised or cauterized and the abdomen should not be opened deliberately at some point of election until penetration has been definitely determined. It is needless to say the cauterizing should never be done. The probe, in fact, should be eliminated from the paraphernalia of the military surgeon. I have seen a number of small and apparently trivial wounds, of the loin and lumbar region particularly, in which either a careful examination or time would show that the missile had penetrated the abdomen. I recall seeing a young officer, being treated for gas poisoning of slight degree in a field hospital, who made very light of a small wound in the left loin; but examination made one suspicious of abdominal penetration, and a few hours later, when he had been transferred to an evacuation hospital and operated on, the suspicion became a certainty.

It can truly be said, then, that to lay down definite rules for action in these cases is difficult, and that experience and judgment, and above all a careful examination of each case, are of prime importance.

Many more lives are lost in this field by "not wasting time in trying to make a diagnosis" and operating at once than by wasting the time in study of the case. It is not so much a question of diagnosis as of determin-

² Nageotte, J., and Sencert, L.: *Compt. rend. Soc. de biol.* 82: 45, 1919.

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, June, 1919.

ing whether or not the abdomen should be opened. In this connection there comes to mind that interesting group of combined chest and abdominal wounds—perforations of the diaphragm—in which the surgeon probably has the greatest difficulty in determining his action. It is surprising in how many cases of gunshot wound of the lower chest or those in which a missile lies in or on the diaphragm, the patient will present symptoms which would certainly suggest an abdominal penetration: particularly abdominal rigidity, sometimes later abdominal distention, and frequently hiccup. I can recall six such cases in one evacuation hospital last summer, in any one of which operation might have seemed justified, but in which all six patients recovered without operation.

Still another type of these combined chest and abdominal wounds was that in which the missile penetrates the abdominal wall, perforates the liver and diaphragm, and lodges in the thorax. If the injury is confined to the structures mentioned, and the missile, as disclosed by roentgenoscopy, is not large, no immediate operation should be performed; but the question always came up as to the possibility of injury of the colon or stomach. The probable course of the missile, as indicated by its point of entrance and its location, was of the greatest help in many of these cases. My own rule was not to operate unless there was present a pretty definite indication of injury of a hollow viscus. The wound of the liver and diaphragm alone, except when made by a large foreign body or accompanied by a sucking wound of the chest, was not considered as calling for an immediate operation. I have often regretted operating and suggesting operation in these cases, but I cannot recall a single case in which I regret not having operated or recommending such a course. The situation here can be summarized by saying that if one is fairly certain that the hollow viscera have escaped injury, no operation should be done.

What about hemorrhage? In cases of hemorrhage from the liver caused by gunshot wounds, a few patients are saved by operation, many are not benefited, and not a few are made worse. I believe that nature is more likely to stop bleeding from a gunshot wound passing through the liver than is the surgeon. In some of these cases the missile has injured the kidney as well as the liver and diaphragm, and here the hemorrhage can and should be controlled, or the kidney removed.

TECHNIC

In regard to the technic of abdominal operations I think there is little to be said, for the war has, I believe, brought about no important changes. Perhaps an exception to this statement can be made in regard to drainage. The rule of closing the abdomen without drainage became established by our allies early in the war, and I believe is a good rule. The war has certainly shown that drainage of any wound is a frequent cause of its infection, and the discontinuance of the abdominal drain represented the application of this general rule to abdominal cases. There are, however, many cases, especially of wounds involving the large intestine and bladder, in which it would have been foolish not to drain.

An observation which I made, after a few months' service in a British base hospital in France, was that although many men with gunshot wounds of the abdomen were admitted in good condition a week or ten days after operation, yet a number of them later devel-

oped an infection of the wound and it had to be laid wide open. This occurred so often that later in my own work at a British clearing station I followed the plan in every instance in which evacuation was necessary within ten days—and this was true in most cases—of closing all the layers of the abdominal wall excepting the skin and placing sutures through the skin which could be tied later, if no infection occurred. I learned from Brewer that he had reached the same conclusion and followed the same practice. These late infections, I believe, occurred from the skin, and they were also frequently seen after complete closure of the chest and knee-joint wounds. Of course, in the latter two situations it is much more difficult to close off the cavity thoroughly, without closure of the skin, than it is in the case of abdominal wounds. I am sure from my personal experience that the late closure of the skin prevented an infection in many cases. It is true that the late infection of the abdominal wound practically never gave rise to an infection of the peritoneal cavity, whereas such an infection in a chest wound or in a wound of the knee-joint almost invariably resulted in an infection of the underlying cavity. My impression is that when an abdominal drain is employed, it should be a loose gauze drain covered with rubber dam or rubber tissue. The hard, rigid, rubber tubing, or uncovered gauze drains are much more apt to give rise to dense adhesions, which may later produce obstruction or, by pressure, necrosis.

MORTALITY

The mortality in gunshot wounds of the abdomen was extremely high, and a large proportion of this mortality occurred on the field or before the patient reached an advanced operating center, and hemorrhage and shock were its two most potent causes. But the mortality in those cases in which the wounded did reach the operating center was also high, largely for the same reasons, but often because the patient suffered from multiple wounds, the repair of which meant prolonged anesthesia and increased shock. From what I have seen of the late results, I should say that the mortality was not so high as might be expected from late complications in the case of those who recovered from the primary effects of their wound and the operation.

A common observation was that the prisoners with abdominal wounds seemed to stand operation better than our own soldiers, and that the mortality among them was not so high. This, I believe, was due to the fact that they were not operated on with the promptness, I may say haste, that was exercised in the case of our own men. If this observation is correct, the inference is obvious: that it is a mistake to operate on gunshot wounds of the abdomen until the patient has recovered from the shock sufficiently to stand operation, unless the shock is due to hemorrhage. To determine whether the shock is due to hemorrhage was, in many instances, very difficult; but when it was not due to hemorrhage, much better operative results were obtained by waiting. All of the patients, of course, have lost a certain amount of blood; and the important question to decide is whether the bleeding is continuing. One cannot resort to exploratory laparotomy with the same impunity that he would in civil life, because in most instances the patient is suffering from more than one wound, and the operation, which is indicated, must of necessity occupy a much longer period of time and

necessitate the employment of a much larger quantity of the anesthetic agent, two factors which largely increase the immediate operative mortality.

ABSTRACT OF DISCUSSION

DR. EDWARD W. MEREDITH, Pittsburgh: In the case of patients arriving with abdominal wounds which seemed to have penetrated the peritoneum we were able, on account of the absence of rigidity, vomiting and because of the generally good condition of the patient, to say that this patient did not have a penetrating wound of the abdominal cavity. This gave us an opportunity to operate on the wounded men most in need of immediate attention, and to leave the treatment of other patients for a more convenient time. The average time of arrival of patients after injury was twenty hours. In cases in which a hollow viscus was penetrated the question was that of diagnosing peritonitis. We did have abdominal rigidity, some distention and some rise in pulse rate, in addition to the rise that might come from hemorrhage, to aid us in diagnosis. The surgical proposition, therefore, was that of treatment of peritonitis. In none of these cases, except a case of ruptured spleen, was there any question of serious hemorrhage. Four patients with wounds of the chest and abdomen were operated on; two patients had a ruptured spleen; one patient had a ruptured kidney; the fourth patient showed no visceral lesions. The two patients with ruptured spleen died from preoperative and postoperative hemorrhage. All patients were placed in the shock ward, both for observation and resuscitation. After a long ambulance ride, with more or less exposure to cold, with pain and loss of fluids they arrived in a much shocked condition and with depressed vitality. After two or three hours rest in a warm bed there was usually considerable improvement, if anything could be done. Perhaps we used drainage more than Dr. Gibbon did. We found it necessary to drain in 30 per cent. of the cases. The abdominal wall was sutured, with the exception of the skin—following the general rule laid down in the A. E. F., not to suture the skin. We did, however, suture the remaining layers of the abdominal wall. The chest cases in which it was possible that there might be combined abdominal injury were treated conservatively as were all chest cases in our hospital. In wounds of the lower chest wall, in which abdominal distention might be expected, we followed the same rule of depending on rigidity of the abdomen to determine whether an operation should be done. If we could satisfy ourselves that no abdominal hollow viscus had been injured we followed the conservative plan as in the straight chest cases. The difference between military and civilian surgery in cases of wounds of the abdomen is not great. We have nothing special to offer in improved technic in the operation itself. We were handicapped, of course, by the lateness of the patient's arrival. In civilian life this interval would certainly be less than twenty hours. We were handicapped also at times by the rush of patients, and by questioning whether it was advisable to operate in some of the more serious abdominal cases or to operate first on patients who were more lightly injured that they might be restored more quickly. We did not refuse any patient an operation because of the seriousness of his condition. The larger percentage of patients arriving in our hospital reached there in fair condition. Outside of the difference in time of seeing the patient after injury there is little difference between military and civilian surgery.

Is Your Community Fit?—Are your schools provided with medical supervision to control the spread of communicable diseases among the children and to limit the number of sources of contagious diseases which often spread rapidly when carried to susceptible persons? Do your children have the advantage of regular physical examination by a physician? Is there a clinic for the treatment of all the physical defects discovered as a result of this examination? The after-war development of your community will depend largely on the physical fitness of your present school population.—*Pub. Health Rep.*, April 25, 1919.

SURVEY OF THE EPIDEMIC OF INFLUENZA IN THE AMERICAN EXPEDITIONARY FORCES*

WARFIELD T. LONGCOPE, M.D.
NEW YORK

The origin of the epidemic of influenza and its invasion of Europe is still obscure; but it is certain that influenza existed in epidemic form in Spain, France and possibly England, early in 1918, and it may even have been present in endemic form during the previous year. By May, 1918, there was in Spain a widespread epidemic which received much publicity. In April or May there were local outbreaks of the disease, according to the report of the British commission, in the first and second British armies, and by the late spring influenza was present in epidemic form, not only in Spain and in France, affecting both the British and the American armies, but also in Italy, Belgium, Austria and Germany.

Until the complete official records of the incidence of influenza in the American Expeditionary Forces are made available and the statistics of the epidemic published, it is impossible to give figures of similar accurate data which bear on the epidemic of this disease among our own troops in France. A paper by Dr. Ward J. MacNeal,¹ assistant to the director of laboratories and infectious diseases of the American Expeditionary Forces, which recently appeared, is an official report on the epidemic, and contains the official data of interest. Dr. MacNeal kindly allowed me to see the manuscript and to quote from it. Much of what I have to say, nevertheless, must be based on personal observations that are of necessity fragmentary and limited.

As one reviews the history of the epidemic in France, it may be divided into three main periods of outbreaks, with an intermediate and increasing phase bridging the gap between the second and third outbreaks.

The first outbreak appeared in April and May, 1918. It was comparatively mild and spoken of as "the dry fever."

The second outbreak came in September and October, 1918, and formed a part of the terrible pandemic.

The third definite outbreak, according to recent reports, was much less serious, and occurred in January and February, 1919.

The fourth or intermediate phase was represented by scattered cases of influenza and great numbers of respiratory infections, either unaccompanied by pneumonia or associated with an infection of the true lobar type. This phase followed the second great outbreak, and continued during the autumn and winter of 1918-1919.

THE FIRST OUTBREAK

In the first outbreak the earliest recorded epidemic among the American Expeditionary Forces appeared, according to MacNeal, about April 1, 1918, at Rest Camp No. 4 in Base Section 2, near Le Mans. It reached its height, April 22, and cleared, May 5. In May, 1918, a second outbreak of influenza was reported from the Quartier de Beaumont, France, which lasted from May 1 to May 24, and caused 117 cases.

*Read before the Section of Pathology and Bacteriology, Annual Session of the American Medical Association, June 1, 1919.

1. W. J. MacNeal, W. J. The Epidemic of Influenza in the American Expeditionary Forces in France and Italy, *Am. J. Hyg.*, 24: 1-17, July, 1919.

During this month another epidemic occurred at Chaumont, and from this time until July, more or less extensive epidemics appeared throughout the entire American Expeditionary Forces. The disease was likewise prevalent at this time among the French population and in parts of the British army. It is stated by the British commission² that in the first British army, between May 18 and July 2, 36,473 cases of influenza were admitted to casualty clearing stations. It is obvious, therefore, that a widespread epidemic of influenza prevailed throughout France in the spring of 1918, reaching its height in May and June, and subsiding during July and August.

Influenza in this first outbreak was a comparatively mild disease. It was notable on account of the rapidity with which it spread through any organization, on account of the high morbidity rate, the short duration—from two to four days—and the rarity of complications.

The onset was sudden with fever, headache, prostration, pain in the eyeballs, pain in the back, soreness of the muscles, occasional abdominal pain, and rarely vomiting and diarrhea. Epistaxis was common. Occasionally a dryness of the throat with a harsh cough was described. In many cases there were conjunctivitis, slight suffusion of the face and some reddening of the fauces. Muscular tenderness and, more rarely, abdominal tenderness, were present. The fever lasted from two to four days, and convalescence was rapid and almost always uneventful. At this time serious involvement of the respiratory tract was so uncommon that this feature attracted little attention. Only the milder manifestations already mentioned were observed in most localities, though in a few places pulmonary involvement was referred to. In the first British army, it was estimated that in 1 per cent. of all cases coming to the casualty clearing stations, bronchopneumonia developed, from which 10 to 15 per cent. of the patients died. In one epidemic in the Eleventh Engineers, A. E. F., reported by Bradbury,³ among 613 cases of influenza there were ten of severe laryngitis and four instances of bronchopneumonia, from which one of the patients died. It is clear, therefore, that while the first outbreak was generally of a mild character, the upper respiratory tract was not infrequently affected, and occasionally pneumonia recurred as a complication.

THE SECOND OUTBREAK

The second and serious outbreak started during the latter part of August and early in September. In the early epidemics at this time the involvement of the respiratory tract first became alarming. Even by Aug. 18, 1918, in an epidemic at an artillery camp at Valdahom that has been carefully studied by Major Snow and Captain Alan M. Chesney, the disease in most of the 203 patients that were in the hospital presented symptoms of involvement of the upper respiratory tract. Many patients presented signs of the acute emphysema to which Torry and Grosch⁴ have called particular attention in the cases in this country, while the development of pneumonia was not uncommon. Later with the assignment of fresh troops to this camp, the epidemics became much more serious in nature, owing to the frequency of pneumonia. A little later

and during the early part of September, a similar but much larger epidemic took place in an artillery camp near Bordeaux, and though the cases of pneumonia were not very numerous, the mortality among these patients was high.

From the latter part of September until the last of October, the outbreak was at its height. This was approximately the same time that the influenza raged in America. The disease seems to have been the same in the two continents. If it were possible it would be of the greatest interest to compare the incidence of the disease and the morbidity and mortality rate in the different units and organizations in the American Expeditionary Forces with the figures that have been collected from the camps in this country, for in America the troops were under fairly uniform conditions, whereas in France these varied tremendously. It is fair to say, however, that the disease was present throughout France in epidemic form from the base ports to the fighting front. It prevailed particularly, however, first, among the troops at the base ports where during a part of the epidemic transports laden with infected troops were being landed; secondly, in those organizations that contained the largest numbers of replacement troops; and thirdly, in organizations that were being moved on troop trains, where the men were necessarily closely crowded.⁵ The effect which exposure and cold had on the incidence of the disease and its share in determining the prevalence of pneumonia as a complication is not perfectly clear. Troops which were at the front were affected, but it seems highly probable that some organizations were much more severely affected than others which operated under very similar conditions. A study of carefully collected figures and an analysis of the exact conditions would be necessary before one could make any statement regarding this matter. It did seem clear, however, that crowding of influenza patients and their transportation on trains increased the incidence of pneumonia. It will undoubtedly be extremely difficult to determine the morbidity rate in the American Expeditionary Forces, but there is little reason to suppose that it will differ materially from the figures and variations that occurred in this country. An epidemic in one organization which was well separated from other American divisions affected about 20 per cent. of the men. It was further estimated that there were upwards of 1,000 cases of pneumonia, of which 30 per cent. were fatal. This is not very high as compared with the tables which Soper⁶ gives for the camps in this country.

The symptomatology, the clinical course, the pathology and the bacteriology of the disease seem to have been in the main the same in France as they were in this country, and it is, therefore, unnecessary to describe the clinical course which is familiar. At many hospitals that interesting complication, generalized subcutaneous emphysema, which has also been reported from camps in this country, was observed. The mortality in this group was high.

There is a second group of cases to which attention must be drawn. In these meningococci were obtained in culture from the sputum, the blood and in enormous quantities from the pneumonic lungs at necropsy; and it seems highly probable that the meningococcus played some part in the epidemic as a secondary invader and

must be classed as such with the various types of pneumococcus, *Streptococcus hemolyticus* and *Staphylococcus aureus*. The etiology of the disease and, therefore, the position of the influenza bacillus in relation to it, are outside the present discussion. There is one other group of cases which was common in the American Expeditionary Forces, but to which reference has rarely been made. These are the cases of influenzal pneumonia running a prolonged or subacute course. In many of these patients, signs suggestive of lobular pneumonia with extensive bronchitis persisted for weeks and were frequently confused with tuberculosis. It is highly probable that some of these patients had developed bronchiectasis.

OTHER OUTBREAKS

The second and terrible outbreak subsided during the early part of November. The third outbreak of influenza is reported as occurring in January and February of 1919; but since very few data are available concerning this epidemic, I shall not discuss it here.

Between the second and third true outbreaks there occurred what I have termed the fourth or intermediate phase of this epidemic; and though the infections during this period must be considered as a sequel to, rather than a part of, the influenza epidemic, they nevertheless have an important bearing.

With the subsidence in November of the great outbreak, respiratory infections of all types became extremely common, and though it was difficult to differentiate many of these infections from influenza, the large majority did not conform to the clinical picture which had previously been familiar. Laryngitis, tracheitis and bronchitis were extremely common. As a rule, the infections ran a fairly prolonged course with slight initial fever of a day or two. True lobar pneumonia was not unusual. The lobular pneumonias were less common than before. Many of these patients had previously had an attack of typical influenza. There was a leukocytosis in some of the patients observed. Although it is difficult to come to any definite conclusion as to the position which this intermediate phase bears to the general epidemic, it seems highly probable that respiratory infections at this time were not all instances of influenza, but were usually due to the bacteria which had been secondary invaders in the original epidemic. As an explanation of this phase of the epidemic, therefore, one might suggest that the bacteria which as secondary invaders had been widely disseminated and had repeatedly passed through numerous susceptible hosts during the influenza epidemic, had acquired increased virulence and certainly wide distribution and were responsible in themselves for the great prevalence of more or less serious respiratory infections during the few months following the second serious outbreak of influenza.

SUMMARY

It may be said that the influenza epidemic in the American Expeditionary Forces was characterized by three definite outbreaks or peaks: the first between April and July, 1918; the second in September and October, and the third in February and March, 1919. Between the second and third peaks there was an intermediate phase.

The first outbreak was comparatively mild, and at this time involvement of the respiratory tract was unusual and attracted little attention. In the second

outbreak, infection of the respiratory tract with the occurrence of lobular pneumonia became rapidly the predominant feature and was responsible for the high mortality.

These respiratory infections were often associated with the influenza bacillus, but were largely dependent on a secondary invasion of pneumococci, streptococci or, in some instances, even of meningococci.

Following the second peak, there came the intermediate phase during which time the variety of influenza observed in the early outbreaks was rarely seen but respiratory infections of all sorts were extremely prevalent, and one gained the impression that the organisms acting as secondary invaders during the epidemic proper were the primary causes of the bronchitis and pneumonia which was widespread at this time.

The character of the disease occurring in the second peak was the same as that which spread at the same time throughout the United States.

The influenza epidemic affected troops in all parts of France, but prevailed especially at the base ports, in those organizations containing the greatest number of fresh replacements, and in organizations in which the men were of necessity densely crowded together and subjected to excessive fatigue and exposure.

ABSTRACT OF DISCUSSION

DR. ALBERT E. ROUSSEL, Philadelphia: I would like to ask Dr. Longcope what the mortality is in the uncomplicated influenza cases and by that I mean that bronchitis can be accepted in most of these cases as one of the necessary accompaniments of the respiratory tract, what the mortality in these uncomplicated cases is. In the experience of the two epidemics of influenza I think that the mortality of the influenza even of the more virulent type is as yet relatively small—not more than possibly 2, 3 or 4 per cent., that the greater mortality is due to complications often unrecognized so that I do not see why an attempt should not be made to differentiate from influenza proper and its complications. We do know that the pneumonic complications were of a particularly high rate of mortality. Another particular point of interest, I would like to know the proportion of bronchopneumonias to lobar pneumonias. Out of 186 cases of pneumonias in my service there were only seventeen cases of lobar pneumonia. And yet another question, I would like to know the number of cases of kidney involvement of various degrees. No less than 8 per cent. of these cases showed kidney involvement, probably 4 per cent. an acute nephritis.

DR. EDWIN R. LE COUNT, Chicago: It seems to me that some of the members might be interested to know that the first outbreak of influenza was in April, 1918. In Chicago the first postmortems were made by me in the first week of April, 1918. I think there may have been other cases in this country. We did not know at that time what we had. The lungs were full of hemorrhages. It was a reasonable thing to diagnose them as poliomyelitis and meningitis. I sent for my colleagues, Dr. Hektoen and Dr. Davis, to look over it as a new disease. Dr. Davis studied it bacteriologically. We sent everything worth while to a chemist and made histologic examinations, but it was not until the fall that we knew what we had, when we had cases duplicated.

Child Welfare.—Organized recreation is a new idea in comparison with the idea of health. The child of elementary school age should spend at least two or three hours a day in play. Thirty minutes a day is the minimum of time that should be spent in play during the school day. In Camp Sherman it was discovered that 75 per cent. of the men did not know how to play. Two hours a day was spent in organized play as a part of their training.—*School Life* 2:2 (May 16), 1919.

IS EPINEPHRIN INDISPENSABLE TO LIFE?

Epinephrin is produced by the suprarenal glands. As these are generally regarded as indispensable for life, and since epinephrin is a potent physiologic product which can profoundly affect certain muscular structures and the circulation, the discharge of this substance into the blood has come to be regarded as the most prominent feature of suprarenal function. There is no doubt that the suprarenals can at times and under appropriate nervous stimulation secrete unusual amounts of epinephrin into the circulation. Some clinical observers have therefore asserted that certain features of nephritis and arteriosclerosis are due to a sort of suprarenalinemia. Furthermore, epinephrin has been held responsible for some of the physiologic manifestations called forth by fright or other extreme emotions. A recent reviewer of the present status of these contentions that epinephrin is secreted into the blood in supernormal amounts in such emergencies states that the belief has arisen partly from the similarity between the general behavior of an animal following the intravenous injection of epinephrin and during states of extreme excitement. Dilatation of the pupils, bristling of the hair, salivation, rise in arterial blood pressure, inhibition of the intestinal movements, protrusion of the eyeballs, are all symptoms of fear just as they are of epinephrin injection.¹

The assumption that the physiologic reaction to fear and other emotional states is dependent on hypersecretion of epinephrin into the blood—an assertion especially supported by Cannon—has been rendered of doubtful validity, if not actually untenable, by the extensive researches of Stewart and Rogoff and their collaborators at the Western Reserve University School of Medicine. They report that animals in which both suprarenal glands are entirely removed from the influence of the nervous system behave like normal animals when frightened. Therefore, epinephrin appears to have little if any contributory influence in the usual course of events associated with emotional states.

Doubt has already been expressed that such functions as the tone of the muscles and blood vessels are

particularly dependent, as some have argued, on a discharge of epinephrin into the circulation. It has been a tempting hypothesis to assume that changes in blood pressure are brought about by a mechanism in which the secretion of a pressor substance like epinephrin plays a dominant part. But the investigations of Stewart and Rogoff² seem clearly to negate this. They have demonstrated on a number of animal species that it is possible to live indefinitely in good health after excision of one suprarenal and section of the nerve of the other, an operation which either abolishes the output of epinephrin from that suprarenal or reduces it to a small fraction of the normal. The observations have been so numerous and so well controlled that they preclude the assumption of the presence of accessory suprarenals or of any similar factor to account for the results. For the present, physiology may rest with the belief that the liberation of epinephrin from the suprarenals is not indispensable for life and health.

THE CLOTTING OF MILK IN THE STOMACH

It is singularly unfortunate that there are such marked differences of opinion regarding a food as nutritious and unique as is milk. The physician who advises its use is continually met with statements as to the intolerance of individual patients toward it. Usually their idiosyncrasy is described as an inability to digest milk; more rarely there are reports of apparent hypersensitiveness to this food suggesting the familiar anaphylactic responses to other dietary articles. By some who are responsible for feeding the sick, the use of milk is studiously avoided whenever the patient expresses an objection to it. Others, on the other hand, follow the dictum expressed by Richard Cabot:

Any one can take milk. If a person tells me, "I cannot take milk," I always say, "You can if you will take it in a certain way." It is a question usually of flavoring it right or of taking it like soup, with a spoon, with a bite of some carbohydrate substance, cracker or bread, between the sips. I do not think everybody must take milk, but I think everybody can.³

The digestion of milk in the alimentary tract is unique, in contrast with other foods, in that it exhibits the well-known phenomenon of clotting. The clots produced in the stomach vary enormously in size and texture. Sometimes they remain finely flocculent; otherwise they may shrink or coalesce into a hard and leathery mass. It would not be difficult to quote "authorities" for all manner of views respecting the relative digestibility of the precipitated casein in the different forms which it may take in the stomach. Even more varied are the views regarding the clotting or treatment of milk responsible for its clotting

² Stewart, G. N., and Rogoff, J. M.: *J. Pharmacol. & Exper. Therap.* **103**: 1, 1917; Further Observations Showing That Epinephrin from the Adrenals Is Not Indispensable, *Am. J. Physiol.* **48**: 397 (May) 1919.

³ Cabot, R. C.: *A Lesson's Handbook of Medicine*, Boston, Houghton, Mifflin Company, 1916, p. 115.

in the dense or in the finely flocculent state, respectively. It is natural that the hypothesis of the greater digestibility of a finer suspension of protein should have proved more popular on general principles, yet this is by no means the view held exclusively. To attain a desired type of flocculence, various procedures have been advised. Dilution with water, with lime water, or with cereal concoctions finds advocates. The suggestion to boil the milk; to reduce or augment the fat content, as the case may be; to employ preliminary chemical or enzymatic treatment—these and other proposals have been made, from time to time. It is doubtless true that a dozen claims, mostly conflicting, could be discovered in the literature of advices regarding the ideal mode of preparing milk as a food.

A group of investigators¹ at the Jefferson Medical College have discarded the test tube and beaker, and substituted the human stomach in the study of how milk coagulates under physiologic conditions. The cooperation of a normal man who could regurgitate stomach contents at will supplied an unusual facility for such an investigation. The results observed on him are contradictory to much that is traditional and taught. They tell us, for example, that milk drunk rapidly left the stomach sooner and produced a smaller curd mass than milk drunk slowly or "sipped." This is quite as revolutionary as the now admitted assertion that water drunk at meal time is not an unmixing evil, or that the "fletcherizing" of food fails to accomplish any marvels in digestion. Again, it was learned that raw whole cow's milk forms a large, hard curd, whereas boiled milk curds in a much finer and softer form; that the presence of much cream (milk fat) in the milk insures the formation of particularly soft curds which are slow to leave the stomach; that skimmed milk yields a particularly hard curd, owing to the absence of fat; that pasteurized milk shows smaller curds than the raw whole milk but larger than the boiled whole milk, and that cold milk coagulates more slowly than warm milk.

Some of these findings have been reported before.⁵ It would be premature to announce them as the last word on the clotting of milk in the human stomach, or to make them the sole guide to the ways of using milk as food. Thus, the question of the effects of heating milk on some of its physiologic properties, such as the antiscorbutic potency, cannot be ignored in this connection; nor do the texture and form of the curd necessarily parallel any scheme of digestibility. Perhaps this recital will have served a useful purpose if it directs attention to the inadvisability of offhand pronouncements on subjects still so incompletely investigated and imperfectly understood as are the conditions modifying the alimentary digestion of milk.

IMPRESSIONS VERSUS FACTS IN THE TREATMENT OF PNEUMONIA

The value of any method of treatment, whether developed empirically or by a long and laborious course of scientific reasoning and experiment, must rest finally on the outcome of its application to clinical medicine. Furthermore, the analysis of clinical results, either statistical or derived from observations of symptomatology, must also be scientifically controlled. On passing from the laboratory to the clinic, the obligation of scientific accuracy is increased rather than diminished, and with the decrease in control over the individual elements of the experiment, the need for caution in interpretation of results increases proportionately. If the case mortality of a given disease were regularly 100 per cent., and if by the use of a remedy the mortality were regularly reduced to 50 per cent., the number of cases necessary to establish the clinical value of the remedy would be many times smaller than if the untreated case mortality were, say, 75 per cent. And if in the untreated disease it were known that the mortality varied within wide limits, the number of observations necessary to prove the value of a remedy by the statistical method would be still further greatly increased.

Lobar pneumonia presents an unrivaled variability in clinical course, duration and mortality in different epidemics from season to season and in the relation of case mortality to age incidence. The long list of remedies, each with its extremely low case mortality, which have claimed temporary favor and later been discarded, testifies to the difficulty of safe scientific deduction in a disease in which there are so many naturally varying and often imponderable factors.

The difficulties of forming a clinical judgment are in no wise decreased when it is proposed to substitute a biologic product for a drug. The known presence of antibodies in a serum, or the demonstrated protective power of a serum for test animals, may serve to raise one's hopes of success, but do not justify any departure from the most rigorous control of data derived from a study of clinical results. McClellan¹ has recently presented the results in 322 cases of lobar pneumonia in soldiers at Camp Grant in which treatment with immunized chicken serum was given. He concludes that "the low mortality . . . together with the favorable modification of clinical symptoms by the serum . . . would seem to indicate the extension of its use in pneumococcus lobar pneumonia."

Without debating the question as to whether antibodies said to be demonstrable in the serum might reasonably be expected to exercise an appreciable specific effect on the human body when injected in doses of 2.5 c.c. once or twice a day, or whether the

chill and other phenomena observed following its intravenous injection may not have been of a non-specific nature—similar to those observed when other foreign proteins are injected intravenously as has been already shown in pneumonia—it seems desirable to examine critically the deductions of the author to determine how far the carefully made observations justify his conclusions.

The total case mortality was 7.7. Unfortunately the case mortality of untreated control cases, which is obviously required for a scientific statistical study, is lacking. While the mortality is low compared to the general civilian mortality for pneumonia, several factors besides specific treatment undoubtedly entered into the favorable result. The age incidence (from 21 to 30) and the good general health of a selected class of soldiers should yield a lower mortality than is encountered in civilian population. The case percentage of deaths from pneumonia in the registration area, ages 5 to 20 in the years 1911 to 1916, varied between 5.1 and 5.7, and for ages 20 to 40 from 15.5 to 16.9. For ages 20 to 30 the mortality would be somewhere between these, probably above rather than below 10. Complete figures of mortality from lobar pneumonia for 1918 in the army are not yet available, but sufficient data are at hand to show that the mortalities in the several camps varied and that the total case mortality from lobar pneumonia, not associated with influenza or measles, was probably less than in corresponding civilian groups. Thus in published reports the case mortality varied greatly, so that a group of cases in one camp might show a mortality of 6 per cent., and in another a mortality three times as large. The case mortality of pneumococcus pneumonia for the period September, 1917, to March, 1918, will probably average about 10 per cent. Type 1 pneumococcus infections may perhaps be expected to give a slightly lower mortality. The mortality of Type 1 cases in which McClellan applied his treatment was 9.3 per cent. Some camps of the North showed lower mortality than did those of the South. The environment of soldiers previous to entry into the army, whether urban or rural, their race and physical condition, the coincidence of other epidemic disease and the detailed medical care and symptomatic treatment which they received while in hospital all no doubt had some influence on the mortality of pneumonia. When these factors are considered in relation to cases in which McClellan gave his treatment at Camp Grant, the Camp Grant cases might be expected to yield a mortality even lower than the general army average, quite independently of specific treatment.

As a record of achievement in obtaining a low death rate in a serious disease, the report of McClellan deserves much credit; but in the absence of data relative to control cases treated in the same camp, its value as a scientific demonstration of the effectiveness of a

remedy is limited. Continued study and experimentation offer the only hope of progress in the cure of disease, and any rational attempt at therapy deserves a thorough and sympathetic hearing; but in the final trials, before a method is given the clinical stamp of approval, the evidence in its favor should be most carefully weighed and controlled. The joint responsibility of an investigator and his clinical colleagues is large and requires circumspection lest the remedy that appears promising may pass prematurely from their control into the hands of those less interested in science than in financial gain, with the resultant exploitation of the profession and the public.

EXPERIMENTAL ALTERATIONS OF BRAIN BULK

The physical conditions that determine the character of the circulation in the brain have long been regarded to be considerably different from those that obtain in other parts of the body. In most vascular areas, vasomotor changes in the blood vessels are followed by corresponding alterations in the volume of the parts affected. A limb swells or shrinks, respectively, as its blood vessels become dilated or constricted. The brain, on the other hand, is enclosed in a rigid cranium which cannot alter its size in such elastic fashion. Since the blood vessels of this organ are currently believed to project into "a rigid case filled with incompressible material," it is obvious that they cannot, on this hypothesis, contract or dilate without some increase or decrease in the volume of the contents of the cranial cavity. Consequently, a recent writer¹ reflects the trend of present-day opinion when he states that the total volume of blood in the brain must be constant at all times. This is the doctrine formulated by Monroe² more than a century ago, elaborated by Kellie³ in 1824, and accepted by the eminent surgeon Abercrombie.⁴ As a logical consequence, alteration of blood supply to the brain would depend on the change in velocity with which the circulating medium traverses that organ. As Macleod describes the situation, when more blood is required in the brain to compensate for the increased metabolism which we must assume accompanies heightened mental activity, it is not supplied as in other parts of the body by an increase in the capacity of the vessels as compared with those of other vascular areas, but by an acceleration of the circulation through vessels whose caliber remains unaltered. The main factors determining the velocity of bloodflow through the brain must, therefore, be dependent on changes occurring elsewhere in the vascular system.

1. Macleod, J. J. R.: *Physiology and Biochemistry in Modern Medicine*, St. Louis, C. V. Mosby Company, 1918.

2. Monroe: *Observations on the Structure and Function of the Nervous System*, Edinburgh, 1783.

3. Kellie: *On Death from Cold and Congestion of the Brain*, Edinburgh, 1824.

4. Abercrombie, John: *Pathological and Practical Researches on Diseases of the Brain*, Edinburgh, 1828.

Quite recently other possibilities have been indicated through the researches of Weed and McKibben⁵ of the Army neurosurgical laboratory at the Johns Hopkins Medical School. Their researches suggest that the brain should no longer be regarded as incompressible and of fixed volume in accord with the earlier doctrines, but rather as capable of some variation in size. Weed and McKibben have reported the production of alterations in brain bulk independent of changes in volume of the blood in the vascular bed. By producing marked alterations in the osmotic pressure of the blood—through intravascular injection of either hypertonic or hypotonic solutions—changes in the pressure of the cerebrospinal fluid can readily be brought about. But in addition to this, there are striking changes in the size of the brain itself. That these experimental variations are dependent essentially on the factor of osmotic pressure changes of the blood is attested by the fact that no alteration in the volume of the brain follows relatively large doses of Ringer's solution but occurs promptly on intravenous injection of far smaller amounts of distilled water or concentrated salines. Just how this change in osmotic value of the blood affects the brain tissue and alters its volume, the discoverers add, can only be speculated on at the present time. For the purpose of future consideration, we must, therefore, now assume that "the cranial cavity is relatively fixed in volume and is completely filled by brain, cerebrospinal fluid and blood; variations in any one of the three elements may occur, compensation being afforded by alteration in the volume of one or both of the remaining elements."

"CATAPHYLAXIS" AND GAS GANGRENE

The unexpected prominence of gas gangrene as an incident of war wounds has stimulated new investigations in this field of pathology. It is known that the peculiar, abnormal manifestations fail to appear in a large number of cases definitely demonstrated to be infected with the organisms chiefly responsible for gas gangrene, namely, *Bacillus welchii*, *B. oedematiens* and *Vibrio septique*. According to Bulloch and Cramer,⁶ the explanation generally given for the small incidence of gas gangrene in wounds infected with these bacteria is found in the special conditions supposed to obtain in war wounds. The interference with the circulation, the presence of large masses of dead and lacerated muscle, and the presence of dirt and other foreign substances, have all been suggested as factors in making the wounds an exceptionally favorable nidus for the growth of the micro-organisms concerned.

Certain striking experimental facts must be considered in attempting to explain the problem here concerned. When the bacteria of gas gangrene or of tetanus are completely free from their toxins by washing or other methods, they do not produce their specific disease when injected into mice or guinea-pigs. The apparent reason is that the animals dispose of the bacteria partly by lysis and partly by phagocytosis. This defensive mechanism is reputed to be so effective that the bacteria become nonpathogenic when they are injected by themselves. If, however, a small quantity of toxin—even less than is fatal by itself—is introduced along with the micro-organisms, these defensive devices are paralyzed and untoward results follow. In other words, the protective mechanism may be so effective normally that the formation of a toxin in a concentration sufficient to interfere with the normal defensive activities is prevented.

Bulloch and Cramer⁶ have observed that if a small dose of a soluble ionizable calcium salt is injected together with the bacteria or their spores, the specific disease is elicited in a very virulent form. The chlorides of sodium, potassium, ammonium, strontium and magnesium, when injected together with *B. welchii*, are not capable of producing gas gangrene. A direct contact between the bacteria and the calcium salt is not essential. The phenomenon will occur if the bacterial suspension and the calcium salt are injected at different times into the same site, or into different sites at the same time or at different times. The English pathologists conclude that the effect of such injections of calcium salts is to produce local changes leading to local breakdown of the normal defensive mechanism against the bacteria of gas gangrene and tetanus. To this phenomenon the name "cataphylaxis" or "defense rupture" has been assigned.

If "cataphylaxis" is responsible for the unfavorable outcome of infection with the bacillus of gas gangrene, one naturally inquires as to what destroys the body's defenses in the case of those war wounds that take an unfavorable turn. Obviously, salts of calcium cannot always be held responsible. Bulloch and Cramer have found that, of the various foreign bodies tested by them, emulsions of earth were the only ones which frequently, although not invariably, elicited gas gangrene when injected together with the detoxicated bacteria of gas gangrene or their spores. The result is due to a chemical rather than a mechanical factor, since filtered watery extracts were also effective. The damaging potency differs in samples obtained from different localities. Hence the chemical contamination of wounds, as well as their bacterial invaders, may play a part in determining the appearance of gas gangrene. Hence, further, we may understand why it varied with the locality in which the wounds had been received, and was relatively infrequent in certain localities, even though the wounds were infected with

the bacteria of gas gangrene. The hypothesis of the special significance of wound contamination with earth will not explain every case of tetanus and gas gangrene. It adds a new chemical factor for consideration in the mechanism of bacterial infection.

Current Comment

DR. ABRAHAM JACOBI

With Dr. Jacobi's passing, medicine loses one of its foremost figures. Dr. Jacobi enjoyed an unusually long and eventful career, marked by numerous honors at the hands of civic and professional societies. In his capacity as teacher and writer for six decades, he was known to a vast number of physicians throughout the country. His conversation and writings were full of "quaint wit, varied learning and true wisdom." His interest in medical progress and medical knowledge never wavered. Justly held in touching reverence by American physicians, Abraham Jacobi, the Nestor of American pediatrics, lived a full life as beloved physician, noted pediatrician, public spirited citizen, and honored leader.

ERYTHEMA NODOSUM AND OTHER SKIN LESIONS IN TUBERCULOSIS

Tuberculids or paratuberculoses are sometimes defined as a group of skin affections, associated with tuberculosis of other structures of the body, but which do not themselves show the anatomic picture of tuberculosis, to which they consequently seem to have only an indirect relation. Some of the well recognized members of this group are acnitis, lichen scrofulosorum, and acne scrofulosorum. Dermatologists are not agreed as to the causative factor of these lesions, some believing that they are due to "tuberculous toxins," while others hold that the lesions are due to actual reactions to hematogenously distributed tubercle bacilli. Recently Stokes¹ of the Mayo Clinic has discussed the frequent association of erythema nodosum, purpura, and erythema multiforme in patients who suffer from more or less well concealed forms of tuberculosis. This writer believes that such lesions are cutaneous reactions to hematogenously distributed tubercle bacilli, deposited in a hypersensitive skin, and originating in a tuberculous focus, perhaps unrecognized for years. Other investigators have noted the association of tuberculosis and erythema nodosum, and the question remains whether the association is of etiologic significance or merely one of coincidence. According to the definition of a tuberculid, erythema nodosum might be classed perhaps in this group of skin affections, as there is no evidence at hand to warrant the assumption that the lesions are due to hematogenously distributed tubercle bacilli. The work of Rosenow² will be recalled, particularly the production of lesions suggesting erythema nodosum in ani-

mals by the intravenous injection of a diphtheroid gram-positive diplobacillus, which he found in a series of eight cases of erythema nodosum. Stokes points out that "the pathology of erythema nodosum is such that it seems a rash assumption to attribute it to a single type of organism." But he did not make microscopic and bacteriologic studies of the skin lesions in his cases. He did study the cervical or axillary glands in a few cases, and while many glands were found tuberculous, it is not safe to assume that also the associated skin lesion necessarily must have been due to reactions to the tubercle bacillus. The difficulties in the way of bacteriologic and microscopic study of skin lesions in patients are apparent; but such study is, of course, the only way to substantial progress. The association of erythema nodosum and other skin manifestations with tuberculosis is of great interest, and the exact nature of these skin lesions requires further investigation.

SPORTING NOTE

"Nuxated Iron put added power behind my punch and helped to accomplish what I did at Toledo."—Jack Dempsey.

Thus the new world's champion, in large advertisements appearing in last Sunday's papers—at least in such papers as need the money from such sources. The secret is out. We feel that an apology is due to those of our readers who rely on this department for their knowledge of sporting events. We admit to a lack of enterprise in not discovering earlier what was going on behind the scenes in Mr. Dempsey's training camp. But three short years ago, Mr. Willard was telling the public—at the expense of the manufacturers of Nuxated Iron—that that marvelous "patent medicine" was the secret of his easy victories over Jack Johnson and Frank Moran. Now the Honorable William Harrison ("Jack") Dempsey—also at Nuxated Iron expense—"tells the secret" of his training, and explains how "Nuxated Iron" helped him to whip Jess Willard! Ain't science wonderful!

WHEAT AND MEAT IN THE SOLDIER'S DIET

According to the records of food shipped from this country to our army abroad, one third of the American soldier's rations (34.1 per cent.) consisted of flour, 28.2 per cent. of meat, 8.3 per cent. of coffee, 7.3 per cent. of vegetables, 6.8 per cent. of beans, 3.7 per cent. of sugar, 2.5 per cent. of milk, and 1.7 per cent. of fruits.¹ Some fresh vegetables and fruits were purchased abroad. The nutritive "backbone" of this ration thus consisted of flour and meat, the food products that also furnished the bulk of the protein. Considerable discussion has been waged in the past about the question as to the extent to which meat ought to be made a fundamental part of the army ration. It is therefore interesting to note the correspondence of the proportions of cereal and meat actually adopted to the optimum nutritive use recently described for wheat flour by Osborne and Mendel² in

2. Rosenow, E. C.: The Etiology and Experimental Production of Erythema Nodosum, *J. Infect. Dis.* **16**:367 (April) 1915.

1. Where the War Money Went, Treasury Department Loan Organization, quoted from *J. Home Econ.* **11**:269 (June) 1919.

2. Osborne, T. B., and Mendel, L. B.: The Nutritive Value of the Whole Kernel and Its Milling Products, *J. Biol. Chem.* **27**:557 (April) 1919.

their nutrition experiments at New Haven on animals. Having demonstrated that the proteins of the wheat endosperm (which is equivalent to patent flour) are adequate for maintenance but inadequate for normal growth, even when liberal quantities are consumed, they compared the rate of growth made on the proteins of flour alone with that secured from corresponding quantities of protein, two thirds of which was supplied by wheat flour and one third by egg, milk or meat. The results showed how strikingly these supplements enhance the value of wheat flour as a source of protein for the growing animal; and we may infer that its value for the well-being of the adult is also improved thereby. Since milk and eggs are not yet available as staple commodities under wartime conditions, the wisdom of the wheat-meat regimen is manifest.

VENOUS FACTORS IN THE MAINTENANCE OF BLOOD PRESSURE

Every clinician must be interested in the factors that determine the phenomena of the circulation. The measurement of arterial blood pressure in man has become a matter of daily routine for thousands of physicians, some of whom, we fear, fail to realize the real significance of the data which they are collecting so assiduously. Indeed, until quite recently, the causes which operate to maintain the pressure have been sought almost exclusively in the pumping action of the heart, on the one hand, and the peripheral resistance to the outflow of blood from the arteries, on the other. Gradually recognition has come to the significance likewise of the fact that the output of the heart at each beat is dependent on the degree to which the ventricles become filled with blood. Increased frequency of heart beat cannot alter the output into the arteries and increase the blood pressure therein unless the supply from the venous system keeps pace with it. The optimum frequency of the heart beat will thus be dependent on the state of filling of the great veins. In this country, Yandell Henderson in particular has emphasized the significance of what he terms the venopressor mechanism concerned in filling the heart. Recently, also, R. Tigerstedt¹ of Helsingfors has called special attention to the importance of the adequate filling of the great central veins for a proper functioning of the circulation and a maintenance of good pressure when the peripheral arterial factors are unchanged. Any device that leads to an engorgement of these veins with blood almost invariably conditions a consequent rise in pressure. C. Tigerstedt² has shown that this sequence of events can be brought about by immersion baths. Through the pressure exerted by the water on the veins of the periphery and the abdomen, more blood is driven toward the heart, whereupon the output of the heart promptly increases. The extent to which this phenomenon occurs depends, of course, on the degree to which the peripheral vessels are dilated before the bath. R. Tigerstedt has

pointed out that whenever the circulation is impaired because of more or less significant peripheral vascular dilatation, the primary difficulty resides, not so much in this dilatation per se or in a decreased working capacity of the heart, but rather, in the peripheral stagnation of the blood which allows too little to reach the central veins that help to fill the heart.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending July 11, there were 12,388 officers in the Medical Corps, a decrease of 343 from the previous week. The Medical Reserve Corps contained 2,901 officers. The total number of physicians discharged since the beginning of the war is 20,808. The records of the discharge branch of the general staff show the following discharges of officers of the Medical Department from Nov. 15, 1918, to noon, July 10, 1919: 2 brigadier-generals, 63 colonels, 431 lieutenant-colonels, 2,172 majors, 8,697 captains, 10,263 lieutenants, making a total of 21,628 officers discharged to date.

All Temporary Officers to Be Discharged by September 30

All temporary officers of the Medical Corps of the Army, as well as other corps, must be discharged by Sept. 30, 1919, under an order issued by the Secretary of War. Announcement is made that this is a blanket order and not subject to exception. This includes all officers whose commissions were for the recent emergency only.

Award of Cross of the Order of the Bath to American Physiologist

Dr. Walter B. Cannon, professor of physiology at Harvard University, and formerly lieutenant-colonel in the United States Army, who in 1917-1918 cooperated with British investigators in the study of wound shock, has been decorated by the British government with the cross of the Order of the Bath, and given the title of companion of that order. An article by Dr. Cannon on shock, delivered at the last annual session of the Association, appears in this issue.

Personal News of the Services

The honorary degree of LL.D. was conferred on Major-Gen. Leonard Wood, M. C., U. S. Army, by Wesleyan University, recently, and by George Washington University, Washington, D. C., June 18.—The order of commander of the Legion of Honor was conferred on Merritt W. Ireland, Major-Gen., M. C., U. S. Army, Surgeon-General of the Army, and Francis A. Winter, Brigadier-Gen., M. C., U. S. Army, commandant of the Army Medical School at the French embassy at Washington, D. C., in recognition of the services of these officers in the medical department of the Army during the war.—Yale University conferred the degree of Doctor of Laws on Sanford H. Wadham, Lieut.-Col., M. C., U. S. Army, at the commencement exercises, June 18.

Naval Appropriation Bill

The Naval Appropriation Bill passed by Congress carries an appropriation of \$7,500,000 for the medical department of the United States Navy, for the fiscal year beginning July 1, 1919. This is to be used for surgeon's necessities for vessels in commission, navy yards, naval stations, Marine Corps, and for the civil establishment at the several naval hospitals, navy yards, naval medical supply depots, Naval Medical School and Dispensary, Washington, D. C., and for the Naval Academy. It may also be used toward an accumulation of reserve supplies of medical stores. For the contingent expenses of the Bureau of Medicine and Surgery of the Navy \$1,000,000 has been appropriated. The principal items for which this is to be expended are hygienic and sanitary investigations, burial of the dead who die within the United States, automobile expenses and for minor improve-

2. Tigerstedt, C.: Ueber die Einwirkung von Bädern auf den Kreislauf, *Skandin. Arch. f. Physiol.* 36: 322, 1917.

ments at naval hospitals. The sum of \$1,000,000 is also appropriated for the care, maintenance and treatment of patients in naval and other hospitals. The Navy Department is authorized to accept a tract of land on the bay of San Diego, Calif., for the establishment of a Naval Training Station there, provided a site for a naval hospital in Balboa Park is also donated.

Appointments to U. S. Public Health Service

The following nominations in the Public Health Service have been made by the President to the United States Senate:

Dr. Guy M. Parkhurst to be assistant surgeon in the Public Health Service, to be effective from date of oath.

Dr. Clarence A. Ransom to be assistant surgeon in the Public Service, to be effective from date of oath.

Asst. Surg. David Prather to be passed assistant surgeon in the Public Health Service, to rank as such from April 8, 1919.

Asst. Surg. Louis L. Williams, Jr., to be passed assistant surgeon in the Public Health Service, to rank as such from April 8, 1919.

Asst. Surg. Warren F. Fox to be passed assistant surgeon in the Public Health Service, to rank as such from April 9, 1919.

Promotions in the Navy

Among recent promotions in the Medical Corps of the United States Navy are the following:

Medical Insp. Ammen Farenholt to be a medical director in the Navy, with the rank of captain, from the 15th day of October, 1917.

Medical Insp. Middleton S. Elliott to be a medical director in the Navy, with the rank of captain, from the 1st day of January, 1918.

Medical Insp. Dudley N. Carpenter to be a medical director in the Navy, with the rank of captain, from the 1st day of February, 1918.

The following named surgeons to be medical inspectors in the Navy, with the rank of commander, from the 15th day of October, 1917: Archibald M. Feuntheroy, Joseph P. Traynor and John L. Nelson.

The following named surgeons to be medical inspectors in the Navy, with the rank of commander, from the 1st day of January, 1918: Charles C. Grieve, John D. Manchester, James S. Woodward and James A. Randall.

Surg. Robert G. Heiner to be a medical inspector in the Navy, with the rank of commander, from the 1st day of February, 1918.

Surg. Owen J. Mink to be a medical inspector in the Navy, with the rank of commander, from the 1st day of July, 1918.

Surg. Harold W. Smith to be a medical inspector in the Navy, with the rank of commander, from the 8th day of February, 1919.

Awards of Military Cross

The Military Cross has been awarded to the following named medical officers:

Lieut. SAMUEL S. ADAMS, Washington, D. C.; Lieut. MAURICE LINDSEY ALLEN, Calton, O.; Capt. STANHOPE WAYNE-JONES, Baltimore; Lieut. DANIEL EDWARD BERNES, Scranton, Pa.; Lieut. GUY LUTHER HENRY BOYER, Pottsville, Pa.; Lieut. JAMES BROOKFIELD CLINTON; Lieut. JAMES ELMER CROOP, Erie, Pa.; Lieut. DRAYTON HOWARD DOHERTY, Selma, Ala.; Lieut. CARL ELLIS DUNAWAY, Valdesta, Ga.; Lieut. FRANK ALLXANDER EVANS, Baltimore; Lieut. HAROLD ELMER FOSTER, Castle, N. Y.; Lieut. LINWOOD MALONE GABLE, New York City; Capt. HENRY CHRISTIAN GALSTER, Hudson, N. Y.; Lieut. JOHN GREGG, Lieut. ALBERT ALLEN GROSSMAN, Portland, Ore.; Lieut. THOMAS FARRIS HALE, Louisville, Ky.; Lieut. PERRY GATLIN HAMLIN, Philadelphia; Lieut. ABRAHAM IRVING HASKELL, Monroeville, Pa.; Lieut. ALSON JOY HULL, Troy, N. Y.; Lieut. WILLIAM ADDISON JACQUES, New York City; Lieut. ALBERT LESLIE JONES, Weatherford, Texas; Capt. HOWARD FRANCIS KANE, Washington, D. C.; Capt. JOHN EDWARD KELLEY, Chicago; Lieut. BALDWIN LONGSTRETH KEYES; Lieut. CORNELIUS THEODORE MCCARTY, Philadelphia; Lieut. ROY RALPH MCILHENRY, Rogers, Ark.; Capt. WILLIAM ELFORD SAPPINGTON, Hancock, Md.; Lieut. EDGAR FERRIS AND SHIMMIZ, St. Louis; Lieut. JOHN WENLEY SHERRICK, Ann Arbor, Mich.; Lieut. THEODORE HUGHES SWEETSER, New York City; Lieut. GUY DANIEL THIBETTS, Remington, N. H.; Lieut. HARVEY CLAUDE UPHOLGRE, Easton, Pa.; Capt. THOMAS EDWARD WALKER, Cleveland; Lieut. WILLIAM AUGUSTUS WILLIAMS, Monticello, Ga.; Lieut. WILLIAM FREDERICK WILLIAMS, Jr., Chambersburg, Md.; Lieut. JAMES W. ALDRIDGE, Cooneter, Ind.; Lieut. HUGO ALEXANDER, Lieut. WILMOT AYRES, Bedford, Pa.; Lieut. IRVING FRANCIS BARNETT, Chicago; Lieut. WILLIAM HATHFIELD CAINE, Cleveland; Lieut. WILLIAM ANDREW ROBERTSON (HAFIN), Springfield, Mass.; Lieut. EARLE RAY CHAMNESS; Lieut. EDWARD ALBERT CHRISTOPHERSON, Chicago; Lieut. MARY ELLEN COLEMAN, Richmond, Va.; Lieut. FRED COLEMAN, Richmond, Va.; Lieut. GRIFITH ALONZO DEMAY, Lehigh, Neb.; Lieut. LOUIS WILLIAM GIBBY DESPREZ, Tusculum, Ala.; Lieut. ROY ARTHUR DOUGLASS, Huntington, Tenn.; Lieut. JOHN FRANCIS DOOLING, Brooklyn; Lieut. THOMAS LAWRENCE DOYLE, Trenton, Pa.; Lieut. WILLIAM BENEDICT

EVANS, Chester, Pa.; Lieut. LAWRENCE BRYANT FARRIOR, Mobile, Ala.; Lieut. ROY G. GILES, Belton, Texas; Lieut. ALEXANDER JAMES GILLIS, Baltimore; Lieut. THOMAS EVERETT GRIFFITH, Lieut. TORRANCE JOHN HANLON, Donora, Pa.; Lieut. ALLEN GEORGE HEARD, Galveston, Texas; Lieut. WILLIAM YOUNG HOLLINGSWORTH, Bel Air, Md.; Lieut. JAMES HENRY KEELING, Albany, N. Y.; Lieut. ANDREW KNOX, Philadelphia; Lieut. GEORGE SCOTT LAMBERT, Branson, Kan.; Lieut. BERTON MALTBY, Liberty, Mo.; Lieut. ROBERT S. MACGUFFE, Passaic, N. J.; Lieut. WINTHROP ESSEN MCINLEY, New London, Conn.; Lieut. WILLIAM GEORGE MILHOLLAND, Lieut. DANIEL JOSEPH MURPHY, New Orleans; Lieut. CHARLES QUAY NORTH, Punxsutawney, Pa.; Lieut. CLARENCE EDWARD NORTHCUTT, Lexington, Okla.; Lieut. EDWARD LAURENCE PATTERSON, Barnwell, S. C.; Lieut. OSCAR HEDBERG PETERSON, Lamoni, Iowa; Lieut. PAUL JAMES PRESTON, Minneapolis; Lieut. GEORGE H. REDDICK, Wabeno, Wis.; Lieut. SYDNEY S. SCHUCHET, Chicago; Lieut. AUGUS JAMES SMITH, Greenville, Fla.; Capt. WILLIAM LESTER SMITH, Toledo, Ill.; Lieut. FRED OSCAR STONE, Andersonville, Tenn.; Lieut. FENTON TAYLOR, New York City; Major LAURENCE MATHEWS TAYLOR, Lieut. CASSELL CLARK TUCKER, Boston; Lieut. ROBERT VINEYARD, St. Louis.

Distinguished Service Order

The following medical officers are to be Honorary Companions of the Distinguished Service Order:

Lieut. CHARLES EARL FALLET, De Soto, Mo.; Lieut. RAYMOND HORACE GEORGE, Chicago; Lieut. WOOSTER HASSELL HOUSE, Oak City, N. C.; Lieut. FRANK HARRISON MCGREGOR, Mangum, Okla.; Capt. HAROLD JAMES MORGAN, Lieut. GILBERT SEYMOUR OSNICK, New York City; Lieut. GLEN DEWEY RANSOM, Big Rapids, Mich.; Lieut. FRANK E. SCHRAM, Chicago; Major EDWARD GOLDSTEIN, Brooklyn; Capt. GEORGE PATRICK O'MALLEY, Cleveland.

Bar to the Military Cross

The following medical officers have been awarded a Bar to the Military Cross:

Lieut. CORNELIUS THEODORE MCCARTHY, Philadelphia; Lieut. JAMES BROOKFIELD CLINTON, Philadelphia; Lieut. LAWRENCE BRYANT FARRIOR, Mobile, Ala.; Lieut. HAROLD ELMER FOSTER, Castle, N. Y.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

NOTE.—In the following list, L. signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel; Col., colonel, and B. G., brigadier-general.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF HOME OR U. S. GENERAL INTEREST, SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Personal.—The degree of LL.D. has been conferred by the University of California on President Ray Lyman Wilbur of Stanford University.

Osteopathic Bill Vetted.—A bill which would grant full physician's license to persons now practicing osteopathy in California was vetoed recently by Governor Stephens.

Sentenced for Illegal Operation.—Dr. Ephraim Northcott, Redwood City, charged with the murder of Miss Inez E. Reed, a United States Army nurse, by an illegal operation, is said to have been found guilty, July 5, and given an indeterminate sentence of from ten years to life imprisonment.

Medical Board Appointments.—Dr. Alfred J. Scott, Los Angeles, has been appointed a member of the state board of medical examiners, succeeding Dr. Harry V. Brown, Los Angeles, term expired.—Dr. Cyrus J. Gaddis, Oakland, has been appointed a member of the state board of medical examiners, to succeed Dr. Ernest Sisson, Oakland, resigned.

Certificates Revoked.—The certificates of Dr. Franklin T. Duncan, San Francisco, and Robert D. Schultz, Marin County, are said to have been revoked at the meeting of the state board of medical examiners at San Francisco, June 26. Dr. Duncan was charged with malpractice and Dr. Schultz was said to have used the designation of Doctor of Medicine, while his was a license to practice only naturopathy.

Cancer "Specialists" Arrested. Morton M. Winchell, an alleged cancer "specialist" of Los Angeles, according to reports, was arrested, May 14, by the state board of medical examiners on the charge of practicing medicine without a

license. He pleaded guilty and was fined \$250. He is also being held under bail of \$11,000 pending a trial for manslaughter in connection with the death of Mrs. Nellie E. Daniels who is reported to have died, May 8, soon after being treated by Winchell for cancer. Another alleged cancer specialist, A. Edwin Mohr of Pasadena, and a house painter, J. O. F. Haase of San Diego, said to be an ex-convict, were arrested recently for practicing medicine without a license.

COLORADO

Personal.—Dr. John A. Wenk has succeeded Dr. J. H. Hurley as chief resident physician at the Denver County Hospital.—Rea P. McGee, Major, M. C., U. S. Army, Denver, on duty with the A. E. F. in France, has been promoted to the rank of lieutenant-colonel, and has been twice cited for bravery.

Eye, Ear and Throat Men to Meet.—The Colorado Congress of Ophthalmology and Oto-Laryngology will be held in Denver, August 4 and 5, under the auspices of the Colorado Ophthalmological and Colorado Oto-Laryngological societies. The meeting will be held in the Denver County Society Assembly Room in the Metropolitan Building, and Dr. Melville Black, Denver, will preside.

DISTRICT OF COLUMBIA

Graduation Exercises.—Georgetown University School of Medicine and the dental department of the university held their annual graduation exercises, June 28.

Raise Money for New Home.—The Medical Society of the District of Columbia has already raised more than \$50,000 of the \$70,000 required for the erection of a building for the organization on M Street N.W., near Seventeenth Street.

Personal.—Dr. William J. French, Washington, has been awarded the Legion of Honor by the French government, in appreciation of the work done by Dr. French in each of the children's bureaus which he established as a war measure in Paris.—Melville B. Fischer, Washington, who has been chief consultant at Embarcation Camp No. 2, St. Nazaire, France, has been honorably discharged from the service.

Enlargement of Walter Reed Hospital.—Merritt W. Ireland, Major-General, M. C., U. S. Army, Surgeon-General of the Army, appeared before the senate military committee recently and made an urgent appeal for the appropriation of funds with which to purchase about 26 acres of land for the future home of the Army Medical School, Surgeon-General's Library, Army Medical Museum, thus centering all local activities at Walter Reed General Hospital. He estimated that eventually it would be necessary to increase the accommodation of the hospital to about 1,000 beds and have the institution become an establishment for the treatment of special and difficult cases.

FLORIDA

Health Board President Dead.—Honorable Edward M. Hendry, Tampa, former president of the Florida State Board of Health, aged 51, died at the home of his sister in Fort Myers, May 28.

Personal.—Dr. Van H. Gwinn has been appointed acting state health officer, succeeding Dr. William H. Cox, removed; both physicians are of Jacksonville. Dr. Gwinn will serve until the arrival of Ralph N. Greene, Major, M. C., U. S. Army, Chattahoochee, newly appointed state health officer.

Tax Bill Vetted.—May 28, the governor vetoed an act passed by the legislature to amend section 1137 of the general status, providing for a state board of health tax. The causes for veto as stated are: that the bill does not provide sufficient revenue to meet the regular expense of the board, that the language of the act may limit the use of the funds derived so as to embarrass the work of the board and, furthermore, the governor does not believe the revenue to be derived under the terms of the bill will be sufficient for the maintenance and support of the work of the board.

GEORGIA

Venereal Clinic to Be Established.—At a recent meeting of the city council of Macon, it was voted to arrange to finance a venereal disease clinic at the City Hospital, which will be in charge of the hospital commission.

Personal.—Dr. William F. Brummer, health officer of Savannah for twenty years, was presented by the municipality, June 18, with a silver water service.—Dr. George

S. Murray, Columbus, has been demobilized from the Royal Army Medical Corps.—Charles A. Downey, health officer and food inspector of Waycross, has resigned and has been succeeded by Major John R. Scully, who has recently been discharged from the military service.—Dr. James C. Gower has been elected secretary-treasurer of the Park View Hospital, Gainesville, succeeding Dr. Charles W. Larrabee, resigned.

Medical Faculty Changes.—The following members of the teaching staff of the medical department of the University of Georgia, Augusta, have been promoted as follows: Joseph H. Ackermann, assistant professor of obstetrics; Guy T. Bernard, assistant professor of surgery; Charles I. Bryans, associate in ophthalmology, otology, rhinology and laryngology; Asbury Hill, associate in genito-urinary diseases; William J. Cranston, associate in medicine; Robert L. Rhodes, associate in surgery; J. R. Robertson, associate in genito-urinary diseases, and William H. Roberts, instructor in genito-urinary diseases.

ILLINOIS

Sanitary Inspector Returns.—Charles Backus Ball, chief sanitary inspector of the Chicago Department of Health and lecturer for the Army Educational Commission in France, returned to Chicago, July 10.

Illegal Practitioner Arrested.—Mary Zabinsky of 1626 South Morgan Street, Chicago, was arrested by the Illinois Department of Registration and Education and fined \$25 for violation of the medical practice act.

Personal.—Dr. Hartwell C. Howard, Champaign, who was graduated from Starling Medical College, Columbus, in 1859, and has practiced continuously since that time in Champaign, celebrated his ninetieth birthday anniversary, July 12.—Harry D. Orr, Col., M. C., U. S. Army, Chicago, chief surgeon of the Thirty-Third Division, received his discharge at Camp Grant, last week.—Dr. George W. Cusick has been appointed local surgeon for the Illinois Central Railroad at Freeport.

Graduate School Lectures.—The fifth lecture of the graduate summer quarter in medical science at the University of Illinois, Chicago, was delivered, July 11, by Dr. D. Carl Huber, professor of anatomy in the University of Michigan, Ann Arbor, on "Nerve Transplantation."—The sixth lecture of the course was delivered, July 10, by Dr. Charles C. Bass, professor of experimental medicine in Tulane University, New Orleans, on "Malaria with a Special Reference to Its Control."

INDIANA

Telephone Consultations No Longer Free.—Columbus doctors have added 50 cents to the price of all professional calls. Conversations on the telephone of a professional nature will also be charged.

Health Association Organized.—The Public Health Association of South Bend was organized, June 27, and Dan Pyle was elected president, Dr. Walter H. Baker, vice president, Dr. Alta K. Egram, secretary, and Mr. Walter Blossfield, treasurer.

Venereal Clinic to Open.—The city council of Newcastle, at a special session, July 1, voted to cooperate with Henry County in the establishment of a free clinic for venereal disease. Appropriations of \$500 were made by the county council and city council.

Hospital Items.—Plans for a new Wabash County hospital, to be erected at Wabash, at an approximate cost of \$20,000, have been presented for approval by the state board of charities.—There is to be a new tuberculosis sanatorium in Wayne County, located about seven miles south of Richmond.

State Board Loses Suit.—In the Knox Circuit Court, July 5, Judge Thomas B. Coulter found for the defendant in the suit of the state board of medical registration and examination against Dr. George F. Smith, Beclint, the verdict of the court being "not guilty." The charges against Dr. Smith were that he induced the state board to grant a certificate for license by fraud in that he did not have sufficient credits to entitle him to a certificate for preliminary high school work and that he practiced fraud and deception.

Charges Against Physicians.—The coroner of Wayne County is said to have bound Dr. Frederick W. Krueger, Richmond, over to the grand jury on the charge of alleged criminal neglect by throwing a two-day-old infant which he believed to be a monstrosity down a 60-foot embankment on the city dump. The child was found and lived for twelve hours.—Drs. Charles E. Burris, Harrison B. Hulse, Alonzo

S. Neely, Edgar M. Outland, Calvin R. Mims, Indianapolis, Walter M. Byers, Shirley, William McCaen, Quincy, and Lewis L. Williams, Brazil, are said to have been indicted by the Marion County grand jury on the charge of the illegal sale of intoxicating liquors.

Tuberculosis Notes.—The headquarters of the Mississippi Valley regional secretary of the National Tuberculosis Association are to be established in Indianapolis. Arthur J. Strawson, who was executive secretary of the Indiana Tuberculosis Association for two years prior to March 1, 1918, has been appointed regional secretary, and he will have charge of the new district headquarters which will also be the headquarters of the Mississippi Valley conference on tuberculosis. The new regional secretary will have jurisdiction over the states of Indiana, Illinois, Iowa, Michigan, Minnesota, Missouri, Nebraska, North Dakota, South Dakota, Ohio and Wisconsin.—The Adams County commissioners, at their July session at Decatur, unanimously endorsed the proposition of joining with the counties of Wells, Jay, Blackford and Huntington, or any of these counties in the establishment of a sanatorium for the treatment of tuberculosis.

MARYLAND

Personal.—Dr. J. Carroll Monm-nier, who recently served as major in the Medical Corps with the American Expeditionary Forces, has returned to Catonsville to resume practice.—Dr. John S. Green, Jr., Long Green, who was recently discharged from the U. S. Navy, has opened an office at Towson.

MASSACHUSETTS

Hospitals Reopened.—Peter Bent Brigham and the Elks Reconstruction hospitals in which U. S. Army Base Hospital No. 10 has been located, reopened, July 1, for the treatment of War Risk Insurance cases, under the direction of Major Fera K. Sprague, Portland, Me. These hospitals will have accommodation for 800 patients.

Personal.—Dr. Sumner C. Brooks of the Department of Tropical Medicine in Harvard University has been appointed associate professor of physiology and biochemistry at Bryn Mawr College.—Dr. Emily C. MacLeod, Boston, sailed for Serbia from New York to assist in forming hospital organizations in Serbia.—Governor Coolidge has nominated Dr. Joseph Armand Becland, Lynn, for medical examiner (coroner) of Essex County, to succeed Dr. Joseph G. Pugham, resigned.

MISSOURI

Personal.—Dr. Frederick A. Baldwin, Columbia, who has been in charge of the Department of Preventive Medicine of the Missouri State University during the absence of Dr. Mazyck P. Ravenel, in army service, has been appointed pathologist to Wesley Hospital, Kansas City.

State Board Laboratory Transferred.—The Missouri State Board of Health has formally transferred to the Department of Preventive Medicine of the University of Missouri the laboratory works formerly conducted by the department at Jefferson City, and Dr. Mazyck P. Ravenel is now the authorized bacteriologist for the board. Under the new arrangements all diagnosis of typhoid fever, tuberculosis, diphtheria, the examination of water and the like will be carried on at the state university, and treatment for hydrophobia will be administered at the Parker Memorial Hospital at the institution.

MINNESOTA

Hospital Items.—The Oliver Iron Mining Company is preparing to erect a hospital to cost \$270,000 in Hibbing. Physicians of Sandstone have converted the Parish residence into a modern infirmary.

Tribute to Society Members.—A banquet was given at the Minnesota Club, St. Paul, June 21, by the Ramsey County Medical Society to its members who have been in the medical service of the United States or Allies. Of the member list of the society, ninety entered the service and of these, eighty-eight returned. Lieuts. Harry C. McIntosh and Otto L. Winter, both of St. Paul, died in service.

Public Health Associations Organized.—The Isanti County Public Health Association was organized at Cambridge, June 21. Dr. Charles Swenson, Prabhu, was elected president. The Blue Earth County Public Health Association was organized in Mankato, June 21, and Dr. Helen Hughes, Hurler, was elected president.—The Beltrami County Public Health Association was organized at Bemidji, May 29, and Dr. Edwin H. Smith was elected vice president.

Personal.—Drs. S. Marx White, Axel E. Hedback, Minneapolis, and Oscar W. Holcomb, St. Paul, have been appointed members of the state board of health.—L. P. Wolff, St. Paul, has been reappointed a member of the state board of health.—Dr. Henry L. Williams, Minneapolis, has resumed his duties as chief medical officer of the ninth district board of vocational education of soldiers and sailors and marines.—Dr. Henry M. Bracken, executive officer and secretary of the state board of health, St. Paul, was presented with a brass desk set by the women employees of the health office. Dr. Bracken retired from his official position with the state board of health, July 8, to accept a position in the United States Public Health Service.—Walter R. Ramsey, Major, M. C., U. S. Army, Minneapolis, has been awarded a gold medal by the French government for his services to French war refugees in northern France.—Dr. Wenceslaus J. Hovorka, St. Paul, is on trial charged with the illegal selling of narcotic drugs.—Dr. Joseph M. A. Gravelle, Minneapolis, charged with the murder of his wife in June, was found insane by a commission of physicians, June 23, and ordered to be committed to the Hospital for Dangerously Insane, St. Peter.—Dr. Dennis B. Rice, assistant superintendent of the St. Paul City Hospital, has resigned and has been succeeded by Dr. Charles H. Pelton, Bucyrus, Ohio.—Dr. Francis H. Gambell, Thief River Falls, was given a farewell banquet, June 5. Dr. Gambell has started for Siberia, where he expects to remain two years in Red Cross work.—Dr. William B. Wright, Jr., St. Paul, has resumed charge of the Rood Hospital interest in the Mesaba range as superintendent of hospitals.

MISSOURI

Occupational Therapy.—The first issue of the *Bulletin of the St. Louis School of Occupational Therapy* announces that instruction in occupational therapy is being systematically conducted in St. Louis. The course will prepare students to teach occupational therapy to physically and mentally handicapped, and convalescents in public and private institutions, and to meet the demand of the government for reconstruction aides in military hospitals so long as that need exists. The next class opens, September 16, and includes sixteen weeks of craft work and twelve weeks of hospital practice. The cooperation of the Barnes Hospital, the City Hospital and the City Sanatorium offers ample opportunity for practical instruction.

Child Welfare Clinics.—Through the generosity of several public spirited citizens of St. Louis, eight clinics will be established, about September 1, to promote the welfare of infants and children of preschool age. The plan contemplates prenatal work, instruction in the care of the newly born, and watchful supervision until school age. The funds for the first year's work were contributed by private donations, but will be administered under the supervision of the director of public welfare until April, 1920, when the city will take charge of the work and continue it as a municipal undertaking. The donors are Benjamin Gretz, Mrs. Lily Busch, Benjamin and Marcus Harris, Mrs. J. Louis Swarts, William T. Hill, Mr. and Mrs. George Warren Brown, Mrs. Ames Cushman, Mrs. Lon O. Hocker, Mrs. A. Brueggemann and an anonymous donor. The funds will be administered under the direction of Dr. Borden S. Veeder of the Children's Hospital; Mr. John Schmoll, director of public health; Dr. C. H. Shutt, hospital commissioner, and Miss Lyda M. Anderson, chief of the Municipal Nurse's Corps.

NEW JERSEY

State Society Meeting.—The fifty-third annual convention of the Medical Society of New Jersey was held at Spring Lake Beach, June 24 and 25, and the following officers were elected: president, Dr. Gordon K. Dickinson, Jersey City; vice presidents, Drs. Philander A. Harris, Paterson, Henry B. Costill, Trenton, and James Hunter, Jr., Westville; correspondent secretary, Dr. Harry A. Stout, Wenonah; recording secretary, Dr. William J. Chandler, South Orange (re-elected), and treasurer, Dr. Archibald Mercer, Newark. Dr. Alexander Marcy, Riverton, offered a resolution appropriating \$1,000 for a prize essay on "State Social Insurance," open to all medical men of the country.

NEW YORK

Venereal Disease Clinics.—The board of health of Port Chester has decided that a venereal disease clinic should be opened in connection with the child welfare station.—Syracuse has opened a venereal disease hospital in charge

of Dr. Henry A. MacGruer. This building will also be used as a detention hospital.—A venereal disease clinic has been opened in Batavia under the direction of Dr. Frederick D. Carr.

Addition to Letchworth Village.—Governor Smith laid the cornerstone for new dormitories at Letchworth Village, near Thiels, Rockland County, July 9. The new dormitories and other buildings will provide for 840 additional patients. At the last session of the legislature \$880,000 was voted for new construction at the village to make provision for the large number of mental defectives who are without proper institutional care. Dr. Pearce Bailey also made an address in which he urged an extension of the research work at the village, and stated that as a nation we were far behind in taking active measures to handle the problem of the mental defective.

Coordination of Health Activities.—At the meeting held in Utica, June 16, representatives of the committee of hygiene of the board of education; the child welfare committee; home agencies for dependent children; Utica Dispensary; Camp Healthmore; the public welfare committee; Junior League and Day Nursery; the American Red Cross; Associated Charities; Utica Chamber of Commerce and county tuberculosis committee voted to organize a health coordination committee of from five to twelve members. The purpose of this committee is to coordinate the health activities in the community, to promote public health education, to support approved health measures, and to cooperate with the local health authorities in the direction of public health and in meeting emergencies relative to public health.

Personal.—Dr. William G. Bissell, bacteriologist of the Buffalo Health Department, was elected president of the State Sanitary Officers' Association at the annual meeting held in Saratoga, June 25.—Fred M. Meader, New York City, director of the division of communicable disease of the state department of health, has returned from France and has resumed his work. While abroad Dr. Meader served as epidemiologist at Bordeaux and London.—Dr. Linsly R. Williams, Albany, formerly deputy commissioner of the state board of health, returned from his service abroad in June.—Dr. Paul B. Brooks, Albany, acting director of the division of communicable disease in the state department of health, has been designated as chairman of the special committee on drug addiction of the Medical Society of the State of New York.—Dr. Henry L. K. Shaw, Albany, has been appointed a member of the advisory child welfare board of the children's bureau of the federal department of labor.—Dr. Joseph E. Clark, Utica, sanitary supervisor of Herkimer, Madison and Oneida counties, is at St. Luke's Hospital, Utica, convalescing after a surgical operation.

New York City

Personal.—William H. Haskin, Lieut.-Col., M. C., U. S. Army, who has been on duty for two years at the U. S. Military Academy, West Point, was discharged from service, July 1, and will return to his practice, about September 1.—Dr. Pearce Bailey has been appointed chairman of the State Commission for Mental Defectives.

Floating Hospital Opens Season.—The Floating Hospital, which takes sick babies and mothers to the Seaside Home, New Dorp, Staten Island, made its first trip, July 7. The Floating Hospital usually carries about 50,000 babies and mothers during the months of July and August. This year a service of fifty beds has been added, and the night service will be continued whatever the weather. An anonymous donor has promised the Seaside Hospital \$50,000 toward a much needed nurses' home, provided the trustees can raise \$150,000.

Physicians Neglect to Register.—Commissioner Herrick of the state department of narcotic drug control has notified 9,000 physicians, dentists and veterinarians who prescribe or administer habit-forming drugs that they must register or submit to criminal prosecution. July 1, only 8,000 dispensers out of a total of 17,000 had complied with the law. Commissioner Herrick announces that proceedings will be begun against evaders immediately. It is pointed out that two courses of action are open to the department. Licenses may be revoked or evaders may be prosecuted as violators of the public health law.

Greenhut Hospital Closes.—The Greenhut Military Hospital, known as Delabarkation Hospital No. 3, was closed, July 15. The Greenhut Hospital has been the largest military hospital under one roof in the world and has received and evacuated more cases in a shorter time than any other

institution of its kind in the United States. Since the first consignment of wounded arrived from overseas, Nov. 23, 1918, 36,878 patients have entered the institution and have later been discharged or evacuated to hospitals nearer their homes. The record number received in one day was 2,235, and the largest number discharged was 1,638.

Appointments to Staff of Rockefeller Institute.—The board of scientific directors of The Rockefeller Institute for Medical Research announces the following promotions and appointments: Dr. Harold L. Amoss, hitherto an associate in pathology and bacteriology, has been made an associate member; Dr. Oswald T. Avery, hitherto an associate in medicine, has been made an associate member. The following have been made assistants: Miss Clara J. Lynch (pathology and bacteriology) and Dr. Waro Nakahara (pathology and bacteriology). The following new appointments are announced: Drs. Homer F. Swift, associate member in medicine; Francis G. Blake, associate in medicine; Raymond G. Hussey, associate in pathology and bacteriology; J. Harold Austin, assistant in medicine and assistant resident physician; Albert H. Ebeling, assistant in experimental surgery; Ferdinand H. Haessler, assistant in pathology and bacteriology; Thorsten Ingvaldsen, assistant in chemistry; Charles W. Barrier, fellow in pathology and bacteriology; J. Jay Keegan, fellow in pathology and bacteriology; Philip D. McMaster, fellow in pathology and bacteriology. Dr. Alphonse R. Dochez, hitherto an associate member in medicine, has accepted an appointment as associate professor of medicine in the medical department of Johns Hopkins University. Dr. Arthur L. Meyer, hitherto an associate in physiology and pharmacology, has accepted an appointment as associate in physiology in the school of hygiene and public health, Johns Hopkins University.

To Make New York Medical Capital.—An organization, to be known as the New York Association for the Advancement of Medical Education and Medical Science, has adopted a constitution and by-laws and has filed an application for incorporation with the secretary of state at Albany. The project has as its aim the making of New York City a great medical center which shall fill the place formerly occupied by Vienna and Berlin. The constitution of the association names as the four prime objects to be obtained: (1) to improve and amplify the methods of graduate and undergraduate teaching; (2) to perfect plans for utilizing the vast clinical material of the city for teaching purposes and to make use of teaching talent now unemployed; (3) to bring about a working affiliation of the medical schools, hospitals and laboratories, as well as the public health facilities of the city to the end that the best interests of medical education may be conserved; (4) to initiate the establishment of a medical education foundation in New York City whereby funds may be secured to meet the financial requirements of all forms of medical education and investigation. There will be two classes of membership in the organization, one a general membership, including all physicians in good standing, teachers of auxiliary sciences, and investigators of problems related to medicine, the other a corporate membership of medical teachers and medical men with hospital appointments or affiliations. The corporate membership is limited by the constitution to not more than 150. A nationwide campaign to raise \$50,000,000 with which to finance the project will be started immediately. The officers of the association are: president, Dr. Wendell C. Phillips; first vice president, Dr. George David Stewart; second vice president, Dr. Glentworth R. Butler, Brooklyn; secretary, Dr. Haven Emerson; treasurer, Dr. Arthur F. Chace; trustees, Col. Charles H. Peck, Dr. William Francis Campbell, Brooklyn, Dr. John A. Hartwell, Dr. Frederick Tilney, Dr. Otto von Huffman, Dr. Adrian V. Lambert, Dr. Samuel Brown, Dr. James Alexander Miller and Dr. George W. Kosmak, all of New York City.

PENNSYLVANIA

Licenses Revoked.—The State Board of Medical Education and Licensure, June 27, is said to have revoked the licenses of seven medical men for violation of the Harrison Narcotic Law; to have suspended five physicians and to have revoked for three months the license of another physician who is at present serving a sentence for seditions utterances. Those whose licenses were revoked are: Drs. Davis A. Dean, John F. Fox and Oscar Brinn, Pittsburgh; John C. Bateson, Scranton; Thomas R. Francis, Connelville; William H. Rote, Williamsport, and Henry L. Lewis, Erie. Those whose licenses were suspended are: Drs. William P. Buck, Elizabethtown; Henry A. Zeigler, York; George R. Welchans,

Lancaster; Charles G. Hayes, Montoursville, and Walter W. Senn, Williamsport.

"Swat-the-Fly" Campaign.—The war against the house fly is to be carried on more earnestly this year, according to Dr. William C. Miller, Harrisburg, chief of the division of public education of the state department of health, who hopes to reach every schoolchild and housewife, every store owner and employee through the educational drive. Contests in fly-swatting have been organized among the schoolchildren of Harrisburg, and medals have been awarded by the department to the pupils with the largest crops of the obnoxious insects. Dr. Miller is under instructions from Dr. Edward Martin, state commissioner of health, to use the county fairs and the summer schools, the churches and Sunday schools in promoting this health propaganda. Boy Scouts and social workers are both serving, the latter principally in teaching mothers how to make "kiddie coops," and to manufacture simple contrivances to prevent the breeding of flies. According to statistics compiled by the state health department, every year throughout Pennsylvania, the mortality rate among infants who die from intestinal diseases begins to increase in May coincident with the first appearance of the house fly. Month by month, as the flies multiply the death rate from these diseases rises proportionately.

Philadelphia

Personal.—Daniel M. Hoyt, Lieut.-Col., M. C., U. S. Army, recently in command of Base Hospital Unit No. 55, which operated as a part of the Justice Hospital group at Toul, France, has returned.—Morris C. Thrush, chief of the surgical service of the military district near Chateaufaux, France, returned on the *Leviathan*, July 5.—Joseph D. Purvis, Butler, formerly chief of the Section of Hospital Administration of the South Intermediate Zone in France, has succeeded Dr. Clarence V. Clemmer as chief director of the Hahnemann Medical College and Hospital.

CANADA

Deputy Minister of Health.—The Federal Department of Health is in process of organization. It is expected that the deputy minister of health will be Dr. John A. Amyot, professor of public health in the University of Toronto, but no decision has as yet been arrived at.

Hospital Units Arrive Home.—The base hospitals of the University of Toronto, Queen's University, Kingston, and Dalhousie University, Halifax, have arrived in Canada. Only four of the original medical men on the staff of the Toronto Hospital remained with the unit until its return. Col. William B. Hendry, Toronto, was the officer commanding.

Personal.—Dr. Wilfrid Grenfell, C. M. G., is in Ottawa from Labrador.—Dr. Thomas B. Richardson, pension board, Ottawa, is in Toronto for a month's work at the local branch of the board.—Dr. Charles J. C. O. Hastings, Toronto, M. O. H., states that there were only three deaths from typhoid fever in Toronto for the first six months of the present year, and these were all contracted outside of the city. There were eighteen cases in all.—Dr. John A. McCollum has arrived in Toronto from overseas.—Dr. John G. Adams, Montreal, Strathcona professor of pathology and bacteriology in McGill University, since 1892, has accepted the vice chancellorship of the University of Liverpool, England.

GENERAL

Change of Meeting Date.—The date of the meeting of the American Academy of Ophthalmology and Oto-Laryngology in Cleveland, which was to have been held September 1, 2 and 3, has been changed to October 16 to 18.

Consolidation of Health Establishments. The Senate amended the sundry civil appropriations bill inserting a provision calling on the members of the War, Navy, Interior, Treasury and Agricultural departments to report to Congress before December 1, a plan for the consolidation of the various health divisions and bureaus of the government.

Specialists Elect Officers. At the annual meeting of the Kansas City Eye, Ear, Nose and Throat Club, the following officers were elected: president, Dr. Hal Foster, Kansas City; vice presidents, Drs. John D. Bifer, Joplin, and Theodore S. Blakesley, Kansas City, and secretary, Dr. J. Halcomb Lansing, Kansas City. The membership of the Club includes physicians of Arkansas, Kansas, Oklahoma and Missouri. The next meeting will be held October 16.

Specialists Hold Meeting.—At the annual meeting of the American Laryngological, Rhinological and Otolaryngological

Society, held in Atlantic City, May, 1919, the following officers were elected: president, Dr. Harris P. Mosher, Marblehead, Mass.; vice president, eastern section, Dr. Wells P. Eagleton, Newark, N. J.; southern section, Dr. Joseph B. Greene, Asheville, N. C.; middle section, Dr. Samuel Iglauer, Cincinnati, mid-western section, Dr. Frank L. Dennis, Colorado Springs, and western section, Dr. H. Bert Ellis, Los Angeles; secretary, Dr. William H. Hasking, New York City, and treasurer, Dr. Ewing W. Day, Pittsburgh.

Cressy Returns to Serbia.—Dr. William H. Cressy, Grand Rapids, Mich., who has spent two and a half years in the Serbian Service during the war and was commissioned Major in the Royal Serbian Army, has returned to Serbia as director of the medical work of the Serbian Relief Committee. This committee is sending a commission of nineteen physicians and nurses to Southern Serbia under the personal direction of Dr. Cressy. They will be placed at strategic points in their respective districts and will do dispensary work and will conduct a general health campaign. The committee expects to dispatch another medical unit as soon as necessary funds and personnel may be obtained.

Bequests and Donations.—The following bequests and donations have recently been announced:

Jefferson Medical College, \$5,000 for a free scholarship; Rush Hospital, Philadelphia, \$5,000 for free beds; Pennsylvania Training School for the Feeble Minded, Elwyn, \$2,000 by the will of Dr. J. Ewing Mears, Philadelphia.

Hudson Hospital, Columbia, N. Y., and Brooklyn Home for Consumptives, each \$10,000 and Long Island College Hospital, for hospital purposes, \$5,000 by the will of Warren Snyder.

Cooper Hospital, Camden, N. J., for the establishment of five beds in memory of his father, his mother, his two sisters and himself, \$30,000; Camden Home for Friendless Children, and West Jersey Homeopathic Hospital, Camden, each \$5,000 by the will of Oliver D. Wood, Camden.

Adenoids.—As a result of an extensive survey among population centers conducted by the United States Public Health Service it is announced that adenoids are handicapping more than 10 per cent. of American children, and considerable proportion of the defects revealed in medical examinations conducted by draft boards indicated that a large proportion of the defects discovered were unquestionably due to the failure of the parents to pay attention to the physical defects in young children. The Public Health Service has prepared a booklet on "Adenoids," for distribution to parents and school authorities, which tells how the first appearance of adenoids may be detected and points out the means of relief of this condition.

A New Ruling on Narcotic Drugs.—In accordance with the decision of the United States Supreme Court in the *Doremus* case (THE JOURNAL, June 7, 1919, p. 1698), the commissioner of internal revenue in Treasury Decision 2879 has revoked the ruling made in Treasury Decision 2200, May 11, 1915, permitting a physician to dispense or prescribe narcotic drugs in a quantity more than is necessary to meet the immediate needs of a patient. The old ruling permitted a doctor to prescribe a sufficient amount of narcotic drugs to supply the patient for a reasonable length of time. The supreme court holds that an order for morphin issued to an habitual user thereof, not in the course of professional treatment in an attempted cure of the habit, but for the purpose of providing the user with morphin sufficient to keep him comfortable by maintaining his customary use, is not a prescription within the meaning and intent of the act. The commissioner therefore rules that prescriptions for narcotic drugs in a quantity more than necessary to meet the immediate needs of a patient are violations of the law and that the writer of such a prescription, the druggist who fills it and the person obtaining drugs thereunder are all liable regardless of the dosage indicated by the prescription. This means that under the ruling of the federal supreme court physicians prescribing narcotic drugs are permitted to prescribe only such amounts as are necessary for the immediate needs of the patient.

FOREIGN

Public Monument to Zaragoza Physician.—The professors and students of the Zaragoza Medical Faculty have recently erected in the grounds of the Hospital Clinico a monument with bust of the late Dr. Fairen, professor of hygiene and ophthalmology, dean of the faculty and beloved chief of the hospital.

Study of Social Medicine in Spain.—The *Revista Española de Medicina y Cirugía* describes the founding at Madrid of the Instituto de Medicina Social for the study and teaching of questions affecting the practice of medicine from the social or sociologic standpoints. One of the aims of the institute is

to incorporate its principle and methods in the direct administration of public affairs.

Gold Medal to American Red Cross in Italy.—The *Policlinico* relates that an impressive scene occurred at the capitol at Rome when the mayor of Rome, il sindaco Apolloni, presented the officials of the American Red Cross with the gold medal. The ambassador of the United States, Thomas Nelson Page, and the chief of the American Red Cross in Italy, Colonel Bartlett, replied on behalf of the Red Cross to the speech of presentation.

Catalan Medical Congresses.—Our Spanish exchanges mention that the Third Congress of Catalan-Speaking Physicians was to be held the last week in June at Tarragona in eastern Spain. An attendance of about 300 was anticipated. The subjects appointed for discussion are the "Physiopathology of the Abdominal Sympathetic System" and "Treatment of Septicemias." The leading addresses on these subjects were printed and distributed beforehand. Catalan is related to the Provencal of France across the border.

Bassini Reaches the Age Limit.—Prof. E. Bassini retires from the chair of surgery at the University of Padua, having reached his seventy-fifth year. Prof. A. Preti, director of the Bassini Institute for Treatment of Hernia in those unable to pay, has published a short history of the institution as a tribute to Professor Bassini, and subscriptions are being collected to put the institution on a more stable footing. Over 21,000 lire have already been collected. The subscriptions are sent directly to the Istituto Bassini, via Ricordi 1, Milan. Bassini is a senator of the realm.

Honors for Spanish Medical Journals.—The exposition in connection with the recent First National Medical Congress, held at Madrid, awarded a *diploma de honor* to the recently founded medical journals *Progreso de la Clínica y Plus Ultra*, and diplomas with gold medal to the *Revista de Medicina y Cirugía Prácticas*, now in its forty-third year, and to the *Medicina Ibera* which was founded about four years ago with an exceptionally full abstract department. All of these are indexed and reviewed regularly in our Foreign Current Literature Department. The *Siglo Médico* was *hors concours* as its editor was on the organizing board of the congress. Two other medals were awarded, one to a journal devoted to physical education, the other to one just founded for social medicine.

For Aged and Infirm Physicians of France.—Paris has an institution called the *Maison du Médecin*, a medical social gathering place which was founded in 1908, and in 1912 was listed by the state as an *institution d'utilité publique* and granted a subsidy. The social seat is on the rue d'Astorg, Paris, but there is a country home connected with it, a large modern chateau at Valenton, with twenty-five rooms and large grounds where aged and infirm physicians are given a home at low rates (\$80 to 1,500 francs—\$150-\$300). The prevailing high prices have rendered necessary an appeal for more funds, and the *Maison du Médecin*, in the French medical press, is asking for contributions: \$200 makes one a *membre bienfaiteur*, \$40 a *membre perpétuel*, and \$20 a *membre donateur*. Address all contributions to the *Maison du Médecin*, 9 rue d'Astorg, Paris.

Graduate Course on Heart Diseases.—The dean of the *Istituto Clinici* at Milan, Senator Mangiagalli, called on Professor Mariani of the University of Genoa, director of the journal, *Le Malattie del Cuore*, to deliver a course of lectures on the present state of our knowledge of heart disease. This course on cardiology proved extremely popular as Mariani discussed treatment in particular after having shown the various forms of heart insufficiency that may be encountered. He emphasized especially the important aid that may be obtained from the Swedish system of training the heart by passive exercise in the graver cases and against progressive resistance in the others, thus strengthening the heart muscle and accumulating reserve force. A letter recently received from Italy extols the advantages of such courses on cardiology to be held at different points to enable practitioners at large to keep pace with the progress that has been realized of late in the knowledge and treatment of valvular and other affections of the circulatory apparatus. Mariani's clinic at Genoa is known as the *Refugium Cordis*.

Durante's Seventy-Fifth Birthday.—Having reached the age limit, Prof. Francesco Durante retires from the chair of surgery at the University of Rome but retains his seat in the senate. His last lecture was crowded with his present and former pupils and friends, many of his pupils now professors in other universities. He devoted his last address to suggestions for improving the medical curriculum and plan of

teaching. With Guido Baccelli, Durante founded the *Policlínico*, twenty-six years ago, and has always kept his interest in the surgical section, which was his special charge while Baccelli guided the medical section. Both at first combined their efforts in the weekly practical section, now carried on by Prof. V. Ascoli. Durante was always called on to be at least honorary president at nearly every international medical and surgical gathering. The *Policlínico* gives an illustration of the handsome bronze bust, showing the master with his flowing beard, presented to the clinic by his former aids and pupils. The pupils of his last class presented him also with a parchment roll with their signatures and expressed intense gratitude for the way in which he had made it possible for them to complete their training despite their regular military service. Durante's name is connected particularly with progress in treatment of surgical tuberculosis, in the surgery of the skull and brain, and in the science of tumors. His iodine-iodid solution is in constant use.

LATIN AMERICA

Deaths in the Profession.—Dr. E. Mazzini, a leading obstetrician and practitioner of Rosario, Argentina, vice president of the Liga de la tuberculosis and director of one of its dispensaries as also of the training school for nurses and for midwives.

Typhus in Valparaíso.—It is reported from Chile that there have occurred a number of deaths at Valparaíso caused by the epidemic of typhus fever, which has assumed this year an extraordinary virulence. The sanitary authorities have adopted all kinds of precautions to prevent its spread to other places.

Tribute to Dr. Núñez.—The *Sociedad de Estudios Clínicos* held recently an extraordinary session to celebrate the fiftieth anniversary of the graduation of Dr. Emiliano Núñez, the director of the Hospital *Nuestra Señora de las Mercedes*, since its foundation. A gold medal and a diploma were presented to Dr. Núñez on this occasion at Havana.

MADRID LETTER

MADRID, May 10, 1919.

The First National Congress of Medicine in Spain

The First National Congress of Medicine was a great success, the credit belonging to the secretary-general, Dr. Florestán Aguilar, a true Yankee in Spain and a man who has given to his specialty, odontology, an importance not hitherto granted it. The congress was to have been convened November, 1918, but had to be postponed on account of the influenza epidemic.

With all the magnificence that beehives the most splendid European Court, the King of Spain opened the Congress in the Teatro Real. The rostrum was occupied by the Secretary of the Interior, the Mayor of Madrid, the president of the Central University (of Madrid), Dr. Carracido, and the president of the Congress, Dr. Gómez Ocaña, who were surrounded by other prominent scientific personalities. In the royal box were the Queen Dowager and the King's aunt, the Infanta Doña Isabel. Four thousand physicians were in attendance at the opening.

SPANISH NEEDS IN SANITATION

The president of the Congress, Dr. Gómez Ocaña, professor of physiology of the School of Medicine of Madrid, read a splendid address. He said that the need for the Congress was evident from the vast amount of papers, reports, and lectures, which had congested so much the sessions devoted to medicine at the last three meetings held by the Spanish Association for the Progress of Science. The Congress had two purposes: 1. A presentation of the sum of scientific knowledge and its progress and the aspirations of the medical profession of Spain. 2. To obtain a greater solidarity and a wider sphere of action in order to form a great association of the members of the profession in Spain. Other congresses will be held in the different provincial capitals of Spain so that all suspicion of centralization may vanish. He mentioned that the mortality rate of Spain is about twenty-three per thousand, that many deaths are due to malaria caused by the deficient rural sanitation, that many Spaniards die of typhoid fever caused by the inadequate systems of public water supplies, and that many more die of tuberculosis due to congestion and the lack of sunshine and ventilation. While there has not been noted as yet in Spain the diminishing birth rate that is troubling other nations, Dr. Gómez Ocaña repeated the Spanish proverb, "each child

brings to this world a loaf of bread underneath his arm," adding, provided his parents teach him how to work and become prosperous. He asserted that the sanitary problem lacks recognition in Spain. The working class who pay the largest tribute to infection know nothing about it. The socialists hardly mention sanitation in their programs. The middle classes are so engaged in money making that with true Musselman resignation let death arrive even if it comes too soon. The press pays no attention to sanitary questions, and as an instance he cited the fact that some newspapers call *pomerías* (dog doings) the dog bites inflicted on people and which could be avoided if municipal ordinances were enforced. "For our politicians, the proposed sanitary law is a bad omen, for as soon as it is introduced in parliament the government falls out of power, and to be frank about it, we physicians have had so much to do with microbes that we have lost all fear of them and trust entirely too much to the natural defenses of the body." He went on declaring that most physicians who practice in small towns as well as in large ones, are hardly making a living and do not enjoy that inner satisfaction that comes from rendering services which are acknowledged and appreciated. He alluded to the sad scenes which can be seen in many physicians' homes caused by disease, old age and too many children, etc., and end many times in the physician himself or his family finding themselves in destitution. We intend, he said, to form at this Congress a great association with all the advantages that numbers can give, counting with the assistance of the state and taking advantage of all the safeguards that science may furnish.

The Spanish physicians, whose desires were well interpreted by the organizing board of the Congress, were very eager to have associated with them on this occasion, the Portuguese physicians whom they consider as their brethren and the French physicians whom they consider as their teachers. In the name of the Portuguese physicians, Dr. Ceferino Falcón, made some remarks and as the representative of France, Mme. Curie, the illustrious discoverer of radium, addressed the King with words of gratitude for what he had done during the war on behalf of French wounded and prisoners. Addresses were also delivered by Dr. Carracido, the president of the Central University, the Mayor of Madrid who offered the freedom of the city, the Minister of the Interior and finally the King.

THE KING'S ADDRESS

The King delivered an impromptu address, greeting in eloquent words the medical profession which he thanked for the way they spent their lives for their fellow creatures. In their struggle against death the public health authorities, not only lack money as the Secretary of Interior had previously said, but, in the King's words, they also lack hospitals, laboratories and schools where to learn and where to teach medicine. Therefore, he will take on himself the initiative in building up a new school where Spanish-speaking people from across the seas can receive instruction. The cost of a medical school is the same as that of a battleship of 12,000 tons. I want, he said, Spanish medicine to have its battleship. He reiterated his optimism and faith in Spain, which in his words is going forward.

After the meeting the King proceeded to the exhibition connected with the Congress and visited each section and talked with the exhibitors.

The work of the sections furnished a splendid proof of the progress accomplished by the medical profession of Spain, which has now entered all phases of science, bringing with it a spirit of research. This constitutes the greatest triumph that could be wished by all those who regretted the byzantinism of Spanish medicine during the previous generation. We study facts today and cases in particular. Without neglecting generalization, we always start with the fact and have as guides in our work observation and experimentation.

MME. CURIE'S LECTURE

The most remarkable of the lectures was the one given by Mme. Curie, the discoverer of radium, who at the School of Medicine gave a dissertation on radium, its nature and its properties. It was a moment to be long remembered when that distinguished lady assisted by her daughter and surrounded by famous scientists, ended her speech which was greeted by enthusiastic applause. A touching note was added by the Queen Dowager who was prominent in showing her approval of the high gifts of the lecturer. The Queen, who is in mourning for her brothers and relatives killed in the war, embraced Mme. Curie, who was there representing one of the Allied countries. So, as one of our wits said, it is the first time after the war that representatives of the di-

ferent enemy countries have spoken to each other with affection. Science is a great power, indeed.

There were many other conferences given by Spanish and Portuguese physicians and a very interesting one by Dr. Sard, a Spaniard who practices in Paris, where he was the founder and medical director of the Spanish hospital operated there during the war.

RECEPTIONS

Their majesties, the king and queen, gave a reception to all those attending the Congress and their ladies in the evening of the second day of the Congress. With the democracy that characterizes all members of the royal Spanish family, the monarchs talked to all physicians who came near them. As the medical class is undoubtedly the most active of all those which go to constitute this country, the royal family are acquainted with a great many physicians who in turn introduced many others to the king and queen.

Among the banquets special mention should be made of the general banquet with more than 5,000 present. There were also many banquets given by the Madrid members to the foreign guests.

NEXT CONGRESS TO MEET AT SEVILLA

It was decided to hold the next Congress in the city of Sevilla, taking advantage of the Ibero-American exhibition which will be held there next year. At that time an attempt will be made to establish closer relations with the American countries. Physicians coming from the United States will be doubly welcomed as being our guests in addition to being Americans, and their presence will furnish evidence of the present tendency toward union and friendship that inspires all of us.

CUBA LETTER

HAVANA, July 10, 1919.

American Hospital in Havana

One of the most needed institutions today in Havana is an up-to-date American hospital for the benefit of the large Anglo-Saxon colony in this island. In every part of the world where there is a foreign colony, one of the first necessities it feels is the possession of its own institutions, such as churches, schools and hospitals, of which the last mentioned are, perhaps, the most indispensable. New York, for example, has its Jewish, French and German hospitals, and soon will have a Spanish hospital. In Cuba the Spaniards have built their several *quintas* (country houses with gardens or parks) and no doubt feel more at home in them than in the strictly Cuban hospitals, notwithstanding the fact that they are of the same race and language, and it would seem as if the Anglo-Saxon residents of Cuba must feel the same need even more sharply. It is becoming more and more the custom among Anglo-Saxon women to be confined in institutions instead of in their homes. This is even more necessary in Cuba, owing to the difficulty of procuring trained American nurses for the homes on such occasions.

The large number of banks, railroads, sugar estates, and various other foreign corporations employing Americans, Canadians and Britons, would not only find such an institution of great comfort and help, but it would also constitute an insurance for their employees.

The plans for this American hospital are made and the approximate cost will be \$300,000, which includes the site and the building, \$150,000 of which is already available. The American colony of Cuba has received with joy the idea of having its own hospital, and we doubt not that it will soon be a reality.

Latin-American Medical Congress

The last session of the Congreso Médico Latino-Americano held at Lima, Peru, was a great success according to the report presented by Dr. Luis A. Baralt, the Cuban delegate. The next session of the congress will take place in Havana, Cuba, in 1922.

Personal

Dr. Julio F. Arteaga has been awarded the Gordon prize in physiology for his work on "The Localization of the Sensations of Thirst and Hunger." Dr. Arteaga is the editor of the *Revista de Medicina y Cirugía de la Habana*.

Dr. J. Varela Zequera and Ernesto de Aragon have been elected president and secretary, respectively, of the Colegio Médico de Cuba.

Dr. Francisco M. Fernández is the editor of the new *Revista Cubana de Oftalmología*, published in Havana.

Dr. A. Rodríguez Feay, a physician of the medical department of the city of Havana, died, July 8, at his home.

PARIS LETTER

PARIS, June 26, 1919.

War Deafness

At a recent meeting of the Academy of Medicine, Dr. Marage discussed the causes and the duration of the cases of deafness produced by the explosion of shells of large caliber, without any traumatism by a fragment of metal or otherwise. These hypo-acousias are due to the enormous pressure (from 150 to 300 kg. per square centimeter) which is exerted for an exceedingly brief space of time (one hundredth of a second) on the whole surface of the body, and is transmitted through the fluids of the organism to the cortical surface of the brain. Sometimes deafness so produced disappears gradually of itself within two or three months after its causation. Some cases, however, are very serious, and a spontaneous cure is out of the question.

Treatment of Purulent Arthritis of the Knee

At one of the recent sittings of the Surgical Society of Paris, Dr. Tuffier, hospital surgeon and associate professor of the Faculté de médecine de Paris, presented a report on forty-eight cases of purulent arthritis of the knee which Dr. Delzeu of Liège had treated at the field hospital of La Panne by the Willens method; that is, by arthrotomy followed by immediate active mobilization.

Of thirty-one simple cases, the results were as follows: Seventeen were successful, one was partially successful, seven ankyloses resulted, four resections, one death from embolism and one death from septicemia after amputation of the thigh. Of seventeen cases of purulent arthritis following an osteo-articular lesion, the treatment was successful in two cases, partially successful in two, seven cases resulted in ankylosis, five in resection and one in amputation. Successful results are termed those which permitted the patients to flex the joint more than 45 degrees and which promised this as a definite and permanent condition. Partially successful results are those which allow a partial flexure of the joint of from 20 to 40 degrees. The causes of the failure or partial failure of the method are to be sought in the nature of the infection (the streptococcal infections being especially serious) and the extent of the bone lesions.

In certain cases active mobilization cannot be accomplished for various reasons: (1) The age of the patient or the excessive pain (children, especially, not always being able to endure the pain caused by the first attempts at active mobilization); (2) a sort of functional inhibition (of which Delzeu observed four cases out of forty-eight) which prevented any contraction of the extensor muscles of the knee, and (3) a serious lesion of the extensor muscles of the leg—a large or contused wound of the triceps. In these particular cases active mobilization should be replaced by passive mobilization which may give absolutely satisfactory results, but will require special care and watchfulness.

Other factors may enter in to embarrass the therapeutics in the course of the treatment; for instance, certain intercurrent affections, such as influenza and acute sore throat, exert a general influence on the condition of the patient, and even affect the local condition so as to diminish considerably the capacity for active mobilization. Furthermore, after a period of easy active mobilization, complications may arise, especially in cases of purulent arthritis following an osteo-articular lesion; occasionally, too, in cases of simple, penetrating wounds without bone lesion there will be a progressive limitation of movement and a cicatricial retraction resulting in increased stiffness of the joint, even on slight flexure with the classic external rotation of the leg, and finally in ankylosis. In combating these complications the older therapeutic methods come into their rights. A choice must be made between ankylosis and resection. The local condition of the wound and the general condition of the patient are the determining factors in choosing one or the other. If ankylosis can be obtained under good conditions which will permit of a slight flexure, it is always preferable to resection.

Compulsory Notification of Tuberculosis.

The Society of Medical Practitioners, after a discussion of the question of compulsory notification of tuberculosis, has not only had the following resolution, which received the unanimous approval of the society:

The Society of Medical Practitioners, convinced, as it is, of the necessity of waging a bitter fight against tuberculosis, and desirous of rendering support to the government but opposed to the idea of creating medical officials to accomplish a task which naturally falls to the medical practitioners, cannot accept the principle of compulsory notification of tuberculosis until the government shall have introduced such

measures as will give the necessary assistance to indigent patients and their families, such as proper accommodations in hospitals. The society is convinced that, in the meantime, the proper field for the antituberculosis campaign lies in using all possible prophylactic measures in protection of the children; wide publicity as regards the principles and practice of hygiene; combating the alcohol evil; improvements in the character of the homes of the poor, and the amelioration of the social conditions of employment.

The Eight-Hour Day in the Hospitals and the Pharmacies

M. Henri Rousselle, member of the municipal council, recently gave his colleagues the benefit of the investigations and negotiations which he has been carrying on with the city administration in order to bring about the application of the eight-hour day to the hospitals of Paris. The proposed reform concerns more than 12,500 persons. In order to assure the sick the protection that is their due, the present day-shift will continue to devote a morning and an afternoon period to the care of their patients, the morning period to begin at 5 o'clock and the afternoon period at 3 o'clock. This schedule makes it unnecessary for the patients to change attendants, and the physician always has the same personnel to deal with. The night-shift will perform its duties from 11 to 7 o'clock, with the same personnel as at present. However, an "équipe de garde," or provisional shift, will be established, much after the fashion of the "équipe de veille," or watch guard, in order to secure permanence of attendance in the wards during meal times and during the break between the day-shift and the night-shift.

The application of the eight-hour day cannot be made, by reason of multiple difficulties, until the new schedule has been tried out in one or two of the large hospitals.

In this same connection, the Comité intersyndical des pharmaciens of the department of the Seine has informed the public that in response to representations drawn up by the syndicat des préparateurs en pharmacie, the following order of the day has been unanimously adopted by the Comité patronal:

In view of the fact that the pharmaceutical profession is quite distinct from every other profession, and in view of the fact that its hours of duty bear a very close relation to the consultation hours of physicians and to their hours for professional calls, which have not been regulated by law; considering the fact that in the present state of affairs the strict application of the eight-hour law would bring about a condition prejudicial to patients and to the people of Paris; considering, furthermore, that night service has been assured now for a long time by the voluntary offer of services on the part of the pharmacists themselves, the Comité intersyndical, acting in the name of a vast majority of the pharmacists of the department of the Seine, has decided, in view of all the facts, to urge all pharmacists of this department to reduce, from now on, the hours of work for their personnel, keeping in mind, at the same time, the needs of the public in the localities in which they are located, until such time as definite regulations shall be adopted in accordance with law, the purpose of this resolution being to harmonize all interests concerned and also to show respect for both the letter and the spirit of the law.

Withdrawal of Bread Tickets

Our importations of flour for the past few months having been large, the food administration has found it advisable to abolish the use of bread tickets.

Reciprocity Between French and American Universities

L'Union universitaire américaine en Europe elected recently a new executive committee which will enter on its duties, July 1, 1919. Prof. Henry A. Yeomans, dean of Harvard College and exchange professor at the Sorbonne last year, is the chairman.

Since establishing its headquarters in the Royal-Palace-Hôtel, rue de Richelieu, Paris, the union has enrolled about 35,000 students from the various services of the army. This new association of students from the American army in France, composed, as it is, of groups of American students from the fourteen universities of France, has just succeeded in working out a plan whereby it will be possible to send a considerable number of French students for attendance at American universities at the opening of the new school year in September.

Personal

At the meeting, held June 17, the Academy of Medicine elected Dr. Ed. Jeanselme as an active member of the section

of medical pathology, and to serve as hospital surgeon and clinical professor of cutaneous and syphilitic diseases at the Faculté de médecine de Paris.

Exhibit of Prosthetic Appliances

The *Journal officiel* has just published an order in accordance with which practical demonstrations of prosthetic appliances and of agricultural tools and implements intended for the use of those mutilated in war will be held in 1919 on the farms of the society promoting the back-to-the-farm movement. The purpose of these demonstrations is to encourage the manufacture of prosthetic appliances of all kinds, such as will be needed by the war mutilated in order to permit them to continue their agricultural labors. The prosthetic appliances will restore in a measure the function of the amputated member, and the agricultural machines will permit mutilated men to perform all kinds of farm work without making very extensive use of the mutilated member.

French manufacturers and the manufacturers of allied and neutral countries or their representatives residing in France are invited to take part in the exhibit. The appliances and implements will be examined by a commission to be appointed by the departments of agriculture and food administration.

The appliances and machines will be tried out at the exhibit by the mutilated men under the actual conditions of use and will be tested long enough to satisfy the commission as to their advantages and disadvantages. These trials will begin with the harvest and will be continued until after the sowing of the wheat, and in this way the appliances will be tested in connection with almost all kinds of agricultural work.

Researches in Regard to Cancer

The Franco-Anglo-American League Against Cancer (THE JOURNAL, April 27, 1918, p. 1248) recently held a meeting in Paris presided over by M. Justin Godart, former under-secretary of state for the medical department of the army. Godart discussed the purpose of the league, which is primarily to carry on scientific researches in cancer. A committee composed of women will have charge of house investigations and control, including hospitalization of cancer patients. Dr. Hartmann, professor of clinical surgery at the Paris School of Medicine, emphasized the danger which cancer presented at the present time. Every year there die in France 33,000 cancer victims. In Paris alone, in 1913, 3,655 succumbed to this dread disease. Along with tuberculosis, it constitutes one of the two greatest evils that threaten mankind, affecting women even more than men; and that, too, right in the prime of life. The fight against tuberculosis is today at least on the way to a thorough organization. The same is not true of cancer. It is very necessary, therefore, without delay, to instruct the public in regard to the danger which threatens and with respect to the best means of avoiding it. As regards treatment of the cancerous, it is essential that women should learn, under the direction of physicians, just what are the best methods to employ.

An American the Recipient of the Croix de Guerre

Capt. Sterling S. Beardsley, of the American Red Cross, has just received from Marshal Petain the croix de guerre in view of having, at Château-Thierry, after the evacuation of the city, continued the service of his canteen in spite of numerous bombardments and aerial raids.

Personal

At the meeting of June 24, the Academy of Medicine proceeded to elect an active member in the section of legal medicine, in the place of Professor Chantemesse, deceased. Dr. Balhazard, professor of legal medicine at the Paris School of Medicine, was elected by thirty-seven votes out of fifty-four.

At the meeting of June 23, the Academy of Science elected a member in the section of medicine and surgery, to take the place of Professor Dastre, deceased. Dr. Fernand Vidal, hospital surgeon and professor of clinical medicine at the Paris School of Medicine, was elected by thirty-three votes out of fifty-eight.

Dr. Gillot, agrégé professor at the Alger School of Medicine and Pharmacy, has been appointed professor of the clinic for tropical, syphilitic and cutaneous diseases, in the same school, in place of Professor Brault, deceased.

Dr. Breton, agrégé professor at the Lille School of Medicine and Pharmacy, has been appointed professor of hygiene and bacteriology, at the same school, in the place of Professor Calmette, resigned.

Dr. Bué, professor of obstetrics and hygiene of early infancy at the Lille School of Medicine and Pharmacy, has

been appointed professor of clinical obstetrics at the same school, in place of Professor Out, deceased.

Dr. Froelich, agrégé professor at the Nancy School of Medicine, has been appointed professor of infantile and orthopedic clinical surgery, in the same school.

LONDON LETTER

LONDON, June 29, 1919.

The Disproportion of the Sexes

At the National Birth Rate Commission, Commissioner David C. Lamb, director of the emigration department of the Salvation Army, gave important evidence. He said that if a severe spell of unemployment and distress followed the war, there was no hope of an improved birth rate in this country, though no doubt there would be large migration from it. It had been stated that the C 3 classes were adding to the population in larger proportion than the A 1 classes; but in view of the increased publicity given to all matters pertaining to sex relationship during recent years, he questioned very much if the C 3 classes, faced with the prospect of hard times, would continue to be so prolific. The lack of houses would also prevent many of the other classes from marrying, and from that cause also the birth rate would suffer. The disproportion of the sexes, which before the war was causing grave disquietude, had now assumed a menacing aspect. Socially it promoted all sorts of evils. In this time of empire reconstruction, one of the most vital considerations should be the question of a more equal distribution of the sexes throughout the empire. More equal distribution was necessary: (1) that men in the overseas dominions should have the opportunity of getting married; (2) that there might be a higher standard of home life in the dominions affected; (3) for the sake of the women of the motherland who were forced to the repression of their maternal instincts. The progress of Canada and Australia had been hindered for lack of adequate female population, and both in Australia and New Zealand attention had been directed to a declining birth rate. The Salvation Army by means of its emigration department had been doing much to assist women to settle in the overseas dominions, and had emigrated about 10,000 single women. The failures did not amount to 0.5 per cent. Most of the girls had married well, and 70 per cent. of those sent to Canada had married within three years. At present the migration department was waiting for shipping facilities. They had already had applications from hundreds of girls desiring to go to various parts of the dominions. A large number had been employed during the war in munition factories, on the land, and in war work generally. They were mainly between the ages of 17 and 20, and the majority wished to go to Canada, Ontario being particularly favored. It was probable that in future the proportion of single women transferred to the dominions would be considerably greater than it ever had been. It was expected that there would be opportunities overseas for girls who had been working on the land during the war or employed in munition making, or in the various other occupations usually left to men. The housing question would have a big effect on the birth rate and on emigration. It was estimated that there was a lack of nearly 400,000 houses in England and Wales alone. It was reported that there would be a large exodus from Scotland when the shipping restrictions were removed. Was this to be wondered at when 47.9 per cent. of the population were living in houses of one and two rooms, the proportion in Glasgow being 72 per cent.? Scotland's young men and maidens were favoring migration more and more, and the population was declining perceptibly. Something should be done to make Scotland attractive for her own people. But the feudal system still remained in the rural districts, only slowly modified within the last thirty years, and in the cities, towns and villages the depressing and harrack-like tenement continued to spring up in all its unredeeming ugliness.

Ministry of Health

The ministry of health, with Dr. Addison, president of the Local Government Board, as the first minister of health, has been inaugurated. This means the organization under one ministry of all the public health activities which at the past have been administered by several departments. With the creation of the ministry of health, the Local Government Board (the most important of the old departments dealing with public health) will disappear, its functions and staff being handed over to the ministry of health. Similarly the insurance commissioners, who administer the national insurance act, will disappear, their functions being taken over by the new ministry. The first step taken by the minister of

health will be to set up four consultative councils to give advice and assistance in connection with medical and allied services, national health insurance (approved societies work), local health administration, and general health questions. These councils, which will include a number of women, will consist of not more than twenty persons who have had practical experience of the matters for the purpose of which the councils are established. A health program is being drawn up, and it is hoped to get some large proposals ready this year. Apart from the legislative program, it is proposed to push on as rapidly as possible with changes which can be carried through by administrative action. It is hoped to set up a great many maternity and child welfare centers. More centers for dealing with venereal disease are proposed, and the great problem to be faced here is how to conduct them so that the people for whom they are provided will be ready to make use of them.

A Floating School for Physicians

A proposal, made by Dr. Louis Sambon, has excited considerable interest. It is the establishment of a floating school of tropical medicine. The idea is that the students shall embark in a ship fitted up with all the necessary apparatus and laboratories, and shall be taken from one tropical area to another. They will thus be enabled to visit the many fields in which disease flourishes, and, as the passengers will consist of men of every nationality, a new link of world friendship will be forged. Moreover, those workers who are struggling against the various diseases of hot climates will be stimulated by the visits of the "school." It is proposed to visit British, French, American and Italian possessions.

Amendment of the National Insurance Acts

The war has produced a disturbance in the working of the national insurance acts. The government has, therefore, decided to introduce a bill for the purpose of securing that the intention of the national insurance acts is not defeated in certain respects by incidental consequences of the rise in the cost of living due to the war. Under those acts, persons engaged in manual employment come within national insurance without any regard to amount of income or rate of remuneration; but persons who are engaged in non-manual employment are excluded from compulsory insurance when their rate of remuneration is in excess of \$800 per annum. As a result of the increased cost of living, employers have almost universally found it necessary to grant war bonuses to workers, with the result that in a large number of cases (it is believed between half a million and a million) nonmanual workers whose prewar remuneration was less than \$800 per annum receive remuneration exceeding that rate, although the circumstances of their employment are wholly unchanged, and they have not been taken out of the economic status of the persons comprised in the act. If an amendment is not made in the acts, such workers must lapse from insurance and lose all benefits, unless they are entitled and can afford to become voluntary contributors; and even then they are deprived of medical benefit, they are under more onerous conditions as to cash benefits, they lose their employers' contributions, and they must themselves pay their weekly contributions, at an enhanced rate. The injustice would be aggravated by the fact that the distinction between the manual and the non-manual worker is in many cases only technical. It has, therefore, been decided to substitute, for the figure \$800, \$1,250, which corresponds to the rise of wages in the case of nonmanual workers. This proposal has excited considerable apprehension in the medical profession. The hostility of a large number of physicians to the insurance act has never abated, and they are, therefore, opposed to any extension of the act. A deputation from the council of the British Medical Association has been received by the government. While recognizing that there was a case for keeping in insurance persons of the class that Parliament originally intended to be insured, the deputation urged that the simple change of the income limit which was proposed might have the effect of bringing into national insurance, and taking out of the sphere of private practice, a considerable number of persons who had hitherto had no difficulty in employing physicians to treat them as private patients. The representative of the government would not give a pledge to bring forward any provision to restrict the proposed measure to persons who were previously insured, but said that the government would be prepared to consider any practical amendment brought forward by a private member on the subject.

Deaths

Abraham Jacobi * New York City, for more than sixty years one of the most notable figures in American medicine, President of the American Medical Association in 1912-1913, died suddenly at his summer home, Lake George, N. Y., July 10.

Dr. Jacobi was born at Hartum, Westphalia, Germany, May 6, 1830. He studied at the Universities of Greifswald and Göttingen, graduating from the University of Bonn in 1851. He was intimately identified with the German revolutionary movement in 1848 for which he was imprisoned for two years under a charge of high treason. In 1853, while under sentence, he escaped to England and attempted medical practice unsuccessfully at Manchester, and then migrated to America, settling first in Boston and later moving to New York City. In 1860 the New York Medical College established the first professorship of diseases of children and invited Dr. Jacobi to accept this chair. This position he held until 1864, when he accepted a similar position in the University of New York. In 1870 he became professor of pediatrics in the College of Physicians and Surgeons, holding this position for twelve years and retiring as emeritus professor.

During a long career Dr. Jacobi held practically every honor which the medical profession can give to its members. He was twice president of the American Pediatric Society and the first chairman of the Section on Diseases of Children of the American Medical Association. He was president of the Association of American Physicians in 1896; of the New York State Medical Society in 1882; of the New York Academy of Medicine from 1885 to 1889. He was a member and officer of many medical societies both here and abroad. As a contributor to medical literature he is perhaps best known for his work on the intestinal disturbances and the therapeutics of infancy and childhood. His most important papers, monographs and addresses were assembled some years ago in eight volumes in the *Collectanea Jacobi*.

Dr. Jacobi was actively interested in his profession up to the moment of his death; thus at the age of 88 years he attended the annual session of the Association in Chicago and was a conspicuous figure at all of the meetings. Throughout his life he was associated with eminent men, and numerous anecdotes tell of conversations with his early friend Carl Schurz, of meetings with William Osler, Austin Flint and many other noted statesmen and physicians. Although a German by birth, Dr. Jacobi was an ardent American. One of the most significant tributes of his life was the urgent invitation extended to him, October, 1893, to become professor of pediatrics in the University of Berlin, and this position he refused with the historic words "I was, I am, rooted to the American profession that I have observed to evolve without governmental aid out of its own might to become equal to any on the globe."

Dr. Jacobi was perhaps equally well known as a great citizen. He was a formidable opponent of prohibition and an ardent advocate of birth control, and in every other matter of public interest he was a conspicuous character.

On the occasion of his seventieth birthday and each year since, he was especially honored by the medical profession.

Dr. Jacobi was in good health up to but a day before his death. In September, 1918, he had a narrow escape from death when his house at Lake George burned. This year, on his return to Lake George, he occupied the residence of his great compatriot, Carl Schurz, and it was in the house of this famous advocate of human freedom that the great and beloved physician died.

Clement Andariese Penrose * Major, M. C., U. S. Army, Baltimore; Johns Hopkins University, Baltimore, 1897; aged 45; died in the Church Home and Infirmary, Baltimore, July 4, from the effects of septic bronchitis. Major Penrose served as resident physician in Johns Hopkins Hospital in 1897 and 1898, and was on the staff with William Osler, Howard Kelly and W. S. Halstead. He was a specialist in dietetics and functional disorders. He served as surgeon in chief and vice director of the Bahama Expedition in 1903, and as chairman of the food economy commission in 1907. He entered the United States service, Sept. 4, 1917, and served with the British and American Expeditionary Forces, giving especial attention to sanitary conditions in army hospitals and at the front. While engaged in this study in the training camps of the Allies he contracted septic bronchitis, from the effects of which he died.

John Harris Duncan, St. Louis; University of Missouri, Columbia, 1874; Bellevue Hospital Medical College, 1875; aged 66; a member of the Missouri State Medical Association; vice president of the St. Louis Medical Library Association in 1898, and president of the Kansas City Academy of Medicine in 1892; a specialist in dermatology; professor of physiology in the University of Missouri from 1875 to 1883; professor of physiology and dermatology in the University Medical College of Kansas City from 1883 to 1893; then for one year professor of the same subjects in St. Louis College of Physicians and Surgeons; professor of physiology in the Barnes Medical College, St. Louis, from 1898 to 1901, and since that time professor of diseases of the skin and syphilis in the Marion-Sims-Beaumont Medical College, St. Louis; died at his home, June 22.

Frank M. Donohue * New Brunswick, N. J.; New York University, New York City, 1881; aged 49; died at his summer home, Cedar Crest, near Bound Brook, N. J., June 28, from heart disease. Dr. Donohue specialized in surgery, and was surgeon to the John Weld Memorial Hospital, consulting surgeon to the Somerset Hospital, surgeon to the Pennsylvania system, and one of the founders and chief surgeon to St. Peter's Hospital. He served as president of the Middlesex County Medical Society in 1884, 1912, 1914 and 1915, and was a director of the Peoples National Bank, and a trustee of the New Brunswick Trust Company and New Brunswick Savings Institution.

Nathaniel Bowditch Potter * Santa Barbara, Calif.; Harvard Medical School, 1896; aged 49; died at his home, July 4. Dr. Potter was a specialist in internal medicine; and prior to his removal to California, was professor of clinical medicine in his alma mater, chief of the medical department in St. Mark's Hospital, New York City, and consulting physician to the French, New York Nose, Throat and Lung, and the Central Islip State hospitals. He was a fellow of the

ABRAHAM JACOBI, M.D., 1830-1919

* Indicates "Fellow" of the American Medical Association.

New York Academy of Medicine. He went to California in 1918, where he established the Memorial Laboratory and Clinic for the Study and Treatment of Nephritis, Gout and Diabetes, at the Cottage Hospital, Santa Barbara.

George Osborne Hughes, Winnipeg, Man.; University of Virginia, Charlottesville, 1897; L.R.C.P. (London), L.R.C.S. (Eng.), and M.R.C.S. (Eng.), 1899; aged 48; president of the St. Davids Welsh Society; a member of the staff of the Pilgrims' Hospital, Winnipeg, and the Winnipeg Free Dispensary; one of the founders and promoters of the *Western Canada Medical Journal*; died at his home, May 11, from typhoid fever.

Henry Simon Oppenheimer * New York City; College of Physicians and Surgeons in the City of New York, 1874; aged 75; a member of the American Ophthalmological Society, the American Congress of Physicians and Surgeons and a fellow of the New York Academy of Medicine; ophthalmologist to the Montefiore Home; died at his home, July 5.

Anna Howard Shaw, New York City and Washington, D. C.; Boston University, 1885; aged 72; a leader in woman suffrage; president of the National Women's Suffrage Association in 1904 to 1915; who was given the honorary degree of D.D. by the Kansas City University in 1912; died, July 2, at Moylan, Pa., from pneumonia.

Elizabeth Merritt Hooper, Port Huron, Mich.; Woman's Medical College of Pennsylvania, Philadelphia, 1883; aged 59; supreme medical examiner and chairman of the supreme medical board of the Woman's Benefit Association of the Ladies' Order of Maccabees of the World since 1902; died at her home, June 25.

William Wesley Houser, Lincoln, Ill.; Eclectic Medical Institute, Cincinnati, 1859; aged 81; acting assistant surgeon, U. S. Army, and later major, U. S. V., during the Civil War; for seven terms president of the Illinois State Eclectic Medical Society; was struck and instantly killed by a street car in Lincoln, June 23.

Harry S. Jarrett * Towson, Md.; College of Physicians and Surgeons, Baltimore, 1884; aged 58; a charter member and once president of the Baltimore County Medical Society; physician to the Baltimore County Jail; died in Mercy Hospital, Baltimore, June 27, from heart disease.

Elizabeth R. Bundy * Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1884; aged 70; associate professor of anatomy in her alma mater, and for sixteen years visiting physician at the Woman's Hospital, Philadelphia; died in that institution, July 2.

Samuel Malcolm Evans, Bloomfield, Mo.; Kentucky School of Medicine, Louisville, 1898; aged 44; a member of the Missouri State Medical Association; died, May 13, at the Touro Infirmary, New Orleans, after an operation for obstruction of the gallbladder.

Frederick Day Marshall, Chicago; College of Physicians and Surgeons in the City of New York, 1868; University of Michigan, Ann Arbor, 1868; aged 78; a member of the Illinois State Medical Society; a veteran of the Civil War; died at his home, July 6.

Carol Goldenthal * New York City; University of Vienna, Austria, 1906; aged 38; a specialist in dermatology; assistant dermatologist to the City Hospital, and assistant surgeon to the Harlem and Bronx Dispensary; died at his home, July 2, from septicemia.

Frederick Stanton Songer * Kimmidy, Ill.; Milton Sum College of Medicine, St. Louis, 1897; aged 44, a member of the Association of Military Surgeons of the United States; major, M. C. H., N. G., assigned Fifth Infantry; died at his home, July 4.

George Hoffman Parker * Trenton, N. J.; University of Pennsylvania, Philadelphia, 1891; aged 59; assistant physician to Mercer Hospital, Trenton; head surgeon on the Philadelphia and Reading System; died at his home, June 25.

John Reynolds, Salem, Ore.; Mount Medical College, Cincinnati, 1874; University of California, San Francisco, 1876; aged 82; for many years a member of the board of trustees of Willamette University; died at his home, June 22.

John Nesbit Black, Peru, Ohio; University of Western Ontario, London, 1899; aged 59; a member of the Ohio State Medical Association; for two terms governor of Lake County, Ohio; died at his home, June 26, from pneumonia.

Joseph T. Rice, Texarkana, Ark.; University of Alabama, Mobile, 1872, and 67; in November, 1876, town marshal at Texarkana, Texas; later a clergyman of the Baptist Church; died in a hospital in Texarkana, June 23.

Adam S. Todd, Manning, S. C.; College of Physicians and Surgeons, Baltimore, 1891; aged 66; a member of the South Carolina Medical Association; died in the Columbia Hospital, Columbia, S. C., June 26.

Charles B. Hough, Ambler, Pa.; Jefferson Medical College, 1878; aged 64; a member of the Medical Society of the State of Pennsylvania; died from heart disease, July 2, while making a professional call.

Washington Dodge, San Francisco; University of California, San Francisco, 1884; aged 60; one of the survivors of the *Titanic* disaster; died at his home, July 2, from the effects of a gunshot wound.

Dillard Estep Samuel, Wilmington, Ill.; University of Illinois, Chicago, 1908; aged 42; died in St. Mary of Nazareth Hospital, Chicago, June 2, after an operation for appendicitis.

Walton Preston, San Francisco; Rush Medical College, 1881; aged 68; a member of the Medical Society of the State of California; died at his home, July 1.

Julius Parks Clements, Atlanta, Ga.; Medical College of the State of South Carolina, Charleston, 1861; a Confederate veteran; died at his home, June 3.

Charles McMunn Slease, Turtle Creek, Pa.; University of Pittsburgh, Pa., 1905; aged 54; died suddenly in the railway station at Turtle Creek, June 21.

Joseph Marshall, Durand, Mich.; Detroit Medical College, 1878; aged 73; a veteran of the Civil War; died in a hotel in Leavenworth, Kan., June 25.

John Francis Potter, Dow City, Iowa; St. Louis College of Physicians and Surgeons, 1893; aged 62; died at his home, June 22, from diabetes.

William B. Kennedy, Guelph, Ont.; Queens University, Kingston, Ont., 1878; aged 62; died at his home, March 17, from angina pectoris.

John Taylor Tweedy, Tabor, Iowa; Louisville (Ky.) Medical College, 1890; aged 64; died in Mercy Hospital, Council Bluffs, Iowa, June 19.

Virginia Wickliffe Smiley, Carmel, Calif.; Woman's Medical College of Pennsylvania, Philadelphia, 1887; died in San Francisco, July 2.

Walter Junius Hildebrand * Gonzales, Texas; Jefferson Medical College, 1896; aged 45; died at his home, May 20, from pneumonia.

David E. Smalley, Rich Hill, Mo.; Homeopathic Medical College of Missouri, St. Louis, 1873; aged 74; died at his home, June 29.

James Lamar Codie, Lynchburg, Tenn. (license, Tennessee, 1889); a practitioner for thirty-one years; died at his home, June 20.

I. W. Perkins, Jackson, Tenn.; University of Nashville, Tenn., 1882; aged 84; died at his home, June 19.

Marriages

CYRIL AMOS YOUNGS, Lieut. (j. g.), U. S. Navy, to Miss Hazel McCall, both of Kalamazoo, Mich., June 28.

CHARLES ALLEN GRIFFITH, Oak Park, Ill., to Miss Rhoda Marguerite Phillips of East Chicago, Ind., June 18.

HERBERT CHARLES ALLISON, Milner, C. A. M. C., London, Ont., to Miss Ruth H. Davies of Chicago, recently.

JOHN RAYMOND LECOMTE, New York City, to Mrs. Mary Temple Brandt, at Asbury Park, N. J., June 20.

CHARLES DANIEL MCCARTHY, JR., Malden, Mass., to Miss Mary Margaret Galloway of Boston, June 21.

FRANK BARRETT LIVEZEY, Philadelphia, to Miss S. Elsie Nice of Germantown, Philadelphia, June 28.

FRANK ROY BISHAM, Mosinee, Wis., to Dr. Adella Ruby Black of Washburn, Ill., recently.

ALFRED THEODORE JOHNSON, Neenah, Wis., to Miss Sarah Braker of Minneapolis, June 20.

JOHN HANCOCK ABLETTIAN, Chicago, to Miss Julia Goodman of Hamilton, Ohio, July 3.

WILLIAM PERNELL YERGER to Miss Helen Young, both of Mound, Ill., May 14.

MICHAEL SCHWARTZ to Miss Esther Antin, both of Toledo, Ohio, recently.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

DR. DE SANCTIS' RHEUMATIC AND GOUT PILLS A Dangerous, Colchicum-Containing Nostrum

"Dr. De Sanctis' Rheumatic and Gout Pills" are put on the market by Edward Cleaver of London, England. The American agents are E. Fongera and Co., Inc., New York.

During the past few years, THE JOURNAL has received a number of inquiries regarding the composition of these pills, and in every instance has had to acknowledge that it was unable to furnish this information, as no analysis had been made in the Association's chemical laboratory, and available references failed to show that they had ever been analyzed elsewhere. For this reason an investigation of the pills was made and the chemists of the A. M. A. Chemical Laboratory have reported, in part, as follows:

CHEMISTS' REPORT

The various specimens of De Sanctis' pills that were purchased for analytical purposes were found to be round, uncoated, and light brown in color. There was some variation in the color of different lots. A little arrowroot starch was found in each box, used as a dusting powder. The pills were very hard, rather brittle, but quite difficult to powder. The pills were not readily disintegrated by water or dilute acids, even when warmed; when warmed with a dilute sodium hydroxylid solution, they readily disintegrated.

The average weight of a pill was 0.3213 gm., or 5 grains. A microscopical examination of the pills (after they had been reduced to powder) showed powdered colchicum seed in abundance and also traces of arrowroot starch, no doubt from the dusting powder. Since colchicum seed was so abundant, the powder was assayed by the U. S. Pharmacopoeial method for colchicum seed (U. S. P. IX, p. 120). In one assay 3.75 gm. gave 0.0204 gm. colchicin, or 0.54 per cent. In a duplicate 5 gm. gave 0.0234 gm. colchicin or 0.47 per cent., average, 0.5 per cent. The alkaloid obtained had the characteristic appearance and odor of colchicin when separated from the seed under these conditions. From 1 gm. of the powdered pills there was obtained 0.0425 gm. ash, or 4.25 per cent. There were also found about 1/4 grain benzoic acid and about 1/2 grain milk sugar to each pill.

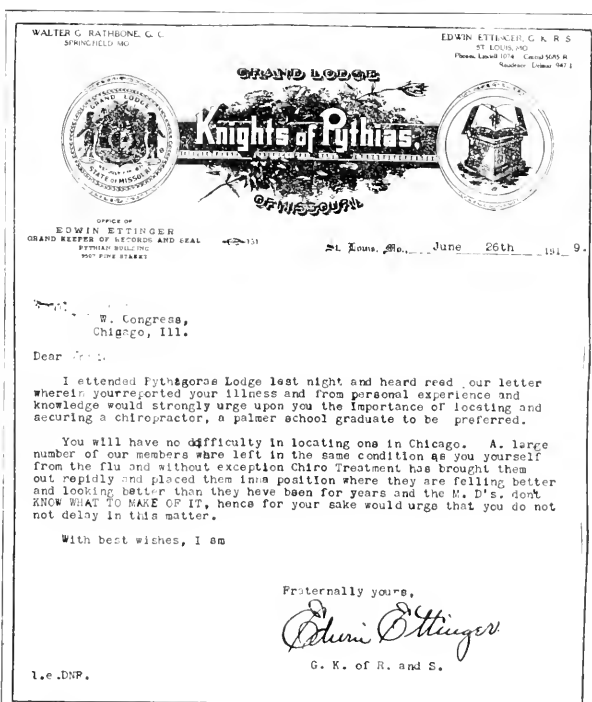

From this examination we conclude that De Sanctis' pills contain powdered colchicum seed, benzoic acid, and sugar of milk. There was also present fatty material which resembled the fat of colchicum seed, but might be, in part, added fatty acid. The percentage of colchicin found indicated that a colchicum seed of high alkaloidal content was used in their manufacture or the possible reinforcement of the pills with colchicum extract or colchicin. De Sanctis' pills are essentially 5 grain doses of powdered colchicum seed.

From the chemists' report it will be seen that the only drug in De Sanctis' pills (present in therapeutic quantities) is powdered colchicum seed. The 1/2 of a grain of milk sugar is doubtless merely an excipient. The fatty acids or fatty matter from colchicum seed that were present are inert, at least in the quantities found in the pills. The only office which fatty acids might perform would be to give the pills

an enteric quality, preventing their absorption until they reach the intestines. Although the entire pills only average 5 grains each in weight, there was present the equivalent of 5 grains of powdered colchicum seed. This indicates, as the chemists have stated, either that a seed of high alkaloidal content is used, or else that the strength of the pills is augmented by the addition of the alkaloid colchicin or, possibly, of colchicum extract.

Here then, we have sold for self-medication an extremely poisonous drug, with no warning of the risk the public runs in using it. While the directions call for "one pill every 8 hours until relieved," it is notorious that the public takes the attitude toward "patent medicines" that, if a little is good, more is better, and the average user of remedies for self-treatment is likely, unless there is some warning, to use his own discretion as to the amount taken.

The individual dose is above that of the average recommended in the United States Pharmacopoeia. Colchicum or its alkaloids—or for that matter, any drug as toxic as colchicum—have no place in preparations of the home-remedy type. In the case of all "patent medicines," public interest demands that the full quantitative formula of the therapeutically active ingredients should be given on the label, for when the public prescribes for itself, it has a right to know what it is taking. Unfortunately, public interest clashes with vested interests and, as usual, vested interests get the better of it. In the case of such dangerous preparations as De Sanctis' pills, if their sale is to be permitted at all, not only should the names and quantities of all therapeutically active ingredients in the mixture be given, but the law should require that the word POISON be plainly printed on the label.

The reduced reproduction above is of a letter sent us by a Chicago physician. The patient who gave him this letter and who received it from the "Grand Keeper of Records and Seal" is suffering from pulmonary tuberculosis.

Correspondence

MEDICAL SOCIETY VISITORS

To the Editor.—The county medical society is the basis of our professional organization. To make it more attractive and more effective strengthens the American Medical Association. It is benefited largely by giving opportunity for interchange of thought among its members. The larger its membership, the more and broader the opportunity; but even the largest society is helped by the presence and words of professional colleagues from outside its own membership.

A good talker, with something of value to talk about, is able to add greatly to the interest and profit of the meetings of any medical society where he is known by name and valuable papers he has published. There are leaders and teachers in medicine who write a few papers of the highest value, who are not often heard in their own local societies, but who might repeat their papers or lectures in a dozen different cities with the highest benefit to the profession. Exchange of lecturers among universities is coming to be practiced more and more, with quickening of interest among students and fuller utilization of the ability of the lecturer. It is time to provide for such exchanges in that educational institution of highest value to the medical profession, the county society.

Nor are the benefits confined to the hearers alone. The lecturer or reader of the paper is benefited by free discussion of the ideas he has to advance. He may be much better posted on his subject than any of his hearers; yet through some different point of view brought out in the discussion, he may get new light on problems to which he has given long and close study. Thinkers welcome the opportunity to place their thoughts before hearers that will be interested in them.

By visitors from outside, many a county medical society, small or large, has found the attendance at its meetings increased, the interest in them quickened, and the literary activity of its own members stimulated, besides getting the benefit of new ideas that might reach it through this channel. If some of the papers crowded into the section meetings of the American Medical Association could be used to stir up local society meetings, both organizations might be benefited. How can such a desirable change in the literary atmosphere be brought about?

Fellows of the American Medical Association travel a good deal, and many of them would be ready to address a medical society of the region visited, if they only were sure of being wanted to do so, and knew when and where such society would meet. What is needed is some agency by which a willing speaker and an interested audience can be brought together.

In the past, certain members of the medical profession have done some of this peripatetic teaching or promulgating of their views. But it has not always been the most modest members of the profession or those to whom the district medical society would be most glad to listen that have put themselves in touch with the officers of societies to proffer such services. The lack of any coordinated plan for the impetus and offering of such services has left the matter in the hands of "pushing," not to say self-advertising writers, and those who are able to get a hearing in medical societies through the activity of personal friends.

Will not some organized body, representative of the American Medical Association take up the important function of bringing speaker and audience in relation with each other? The Council on Medical Education, now becoming active with regard to graduate teaching of medicine, might invite a number of those who by papers they have published have proved that they can produce what is worth reading or hearing, to notify a central bureau when they expect to travel and could address medical societies in other parts of the country.

On the other hand, such societies as would like to hear colleagues from a distance could keep the central bureau informed of that desire and of the times at which regular or special meetings could be held. Then the societies, kept

informed of whom they might secure to address them, could extend a personal invitation to those whom they really desire to hear. With such an assurance that his help is desired by the profession in the city or state to which he is going, many a member would be glad to give his services, who would be very slow to proffer them unasked. The situation is calling for some official body to take cognizance of this need of local societies, and meet it by a proffer of the moderate service required to meet the need.

The need for something of this kind has been forced on my attention in arranging programs for the Denver County and Colorado State Medical Societies.

EDWARD JACKSON, Denver.

USING VARICOSE VEINS FOR INTRA- VENOUS INJECTIONS

To the Editor.—In a recent issue of THE JOURNAL (May 31, 1919, p. 1613), Dr. Kaliski, after enumerating the difficulties encountered in finding suitable superficial veins in some subjects and the practical obliteration of veins in others that have been repeatedly injected, advises the use of the superficial jugular vein for the introduction of saline solutions, arsenical preparations or therapeutic serums. It has been my misfortune after repeated efforts in a number of cases to abandon the intravenous route as I was unable to locate the vein successfully. The situation is a trying and embarrassing one, particularly when the patient has been keyed up to the belief in the potency of the intravenous route. No doubt those physicians that have been in a similar predicament will readily sympathize with their equally unfortunate colleagues.

In a large number of intravenous injections of the arsenphenamin preparations personally administered, my failures to find the veins have been in women only. All of my male patients have been easily and successfully injected in veins at the bend of the elbow. Therefore the advice of Dr. Kaliski to make use of the superficial jugular veins in those patients in whom other sites are not available is an excellent one. I have had no experience with it, but will take the liberty to submit a method of my own which I have used with success in three cases.

My first case was that of a very obese woman in whom I made several ineffectual attempts to inject an arsenical preparation in the veins at the bend of the elbow. I was about to abandon the administration altogether when I recalled that this particular patient had a number of very prominent varicose veins in the lower extremities. I immediately directed my attention to these and selected one that was quite prominent and apparently free in its entire peripheral course. This vein was injected with the solution without incident. The same patient received two more injections in the same vein. There was no local or general reaction. Subsequently two other patients with poorly developed superficial veins at the elbow and who fortunately possessed varicose veins were readily injected. Of course it is obvious that the success of the procedure depends on the presence of varicosities in the lower extremities and the selection of one that has not suffered thrombotic occlusion from a preexisting phlebitis. As women in the main are prone to varicose veins, these should be made use of for intravenous administration when it is impossible to locate a vein in other localities. I have also found that if the varicose veins are not very prominent they can readily be made so by constricting the site above the vein with the cuff of a blood pressure instrument properly inflated.

CHARLES ROSENBERG, M.D., New York.

Signs of Physical Fitness.—A feeling of being refreshed and recuperated on rising in the morning after a customary night's rest, and a feeling of healthy fatigue as bedtime approaches is a sign of physical fitness. The hangover of fatigue in the morning, experienced by so many students and teachers, should be escaped from as fast as possible. On the other hand, a feeling of intellectual keenness and brilliancy in the late evening should be viewed with suspicion. It is an auto-intoxication of the nerves.—Thomas D. Wood, M.D.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THOMAS G. MORTON'S METATARSALGIA

To the Editor:—Who was Morton of Morton's disease fame? Where can I find a short medical biography and other facts concerning his medical activities?

THOMAS TRULSEN, M.D., Tampa, Fla.

ANSWER.—Dr. Thomas G. Morton described metatarsalgia in an article published in Philadelphia in 1876 under the title "A Peculiar and Painful Affection of the Fourth Metatarsophalangeal Articulation." A biography appears in THE JOURNAL, May 30, 1903, p. 1521.

Medical Education and State Boards of Registration

HOSPITAL STANDARDIZATION IN TEXAS

The report of a special committee of the Texas State Medical Association, consisting of Drs. A. C. Scott, chairman, Temple; J. E. Thompson, Galveston, and W. B. Thorning, Houston, appears in the *Journal* of that association of June, 1919. The report follows:

We, your committee, after much study and very careful consideration of the subject, recognize the futility of attempting to lay down hard and fast rules governing the standardization of hospitals in Texas.

We therefore offer the following suggestions as constructive criticism with the hope that future communities will be enabled to still further crystallize opinions of hospital boards and eventually bring about that degree of perfection which is so ardently desired by all.

It is probably beyond argument that the hospital with a "closed staff," i. e., a staff composed entirely of recognized specialists in their respective lines, is the ideal; but as this is manifestly impossible in the majority of Texas hospitals, we make the following recommendations:

First, that where a hospital is operated on the method of the "open staff," or, in other words, where it is open to all doctors in its immediate locality, that its board of directors shall appoint a staff, of a workable number, which shall, from a medical point of view, be known as the governing body of the hospital.

Second, that this staff shall divide itself into committees, for the conduct of the several departments of the hospital. In this connection, we suggest:

(a) That a committee of three compose an operating room committee, whose duty it shall be to acquaint themselves with the character and quality of work being done by different operators, and if, in their judgment, this work is of questionable character or quality, it shall be their duty to report same to the board of directors, with the recommendations that the party in question be denied further privileges of the hospital.

(b) That a like number constitute a committee on x-ray and general laboratory equipment whose duty shall be to see that adequate facilities are afforded for the investigations necessary for correct diagnoses.

(c) A committee should be appointed whose duty shall be to see that all records are kept in a scientific and business-like manner, contain all information pertaining to the welfare of all patients and that all physicians who patronize the hospital shall be required to comply with the regulations regarding the keeping of records.

(d) Another committee should have supervision over the duties of interns and see that they receive adequate instructions.

(e) Another committee should have the duty of aiding the hospital in providing adequate nursing for patients.

(f) In the event of a dissenting voice in any committee, the matter should be submitted to the entire staff, whose final conclusion, by majority vote, should be the recommendation to the board of directors.

(c) We further recommend that all private, non-teaching hospitals desiring classification should possess adequate equipment for scientific work, a complete system of records, a staff in proportion to their capacity, and should invite investigations of their claims for reclassification.

Wyoming February Examination

Dr. H. E. McCollum, secretary of the Wyoming State Board of Medical Examiners, reports the written examination held at Moorcroft, Feb. 12-13, 1919. The examination covered 10 subjects and included 130 questions. An average of 75 per cent. was required to pass. Of the 11 candidates examined, 10, including one osteopath, passed and one, an osteopath, failed. The following colleges were represented:

College	PASSED	Year Gr.	Per Cent.
Bennett Medical College	(1915)	89.1
Chicago Hospital College of Med.	(1914) 82, 82.7, 84.8, 85.4		
Jenner Medical College	(1913)	81.2
Kansas City College of Medicine and Surgery	(1918)	76.3
St. Louis College of Physicians and Surgeons	(1917)	74.8
University of Nebraska College of Medicine	(1919)	84.7

Book Notices

ABNORMAL PSYCHOLOGY: INTERPRETATIONS AND INVESTIGATIONS; CONTEMPORARY AN EXPERIMENTAL STUDY OF SLEEP. By Boris Sidis. Experiment to Determine Co-Conscious (Subconscious) Ideation. By Morton Prince. Colored Thinking. By Fraser Harris. Experiments in Psychogalvanic Reactions from Co-Conscious (Subconscious) Ideas in a Case of Multiple Personality. By Morton Prince and Frederick Peterson. Rationalization of Every Day Life. By Ernest Jones. Personal Impressions of Sigmund Freud and His Work. By James J. Putnam. Dreams and Their Interpretations as Diagnostic and Therapeutic Aids in Psychopathology. By E. Onuf. The Conception of the Subconscious. By Bernard Hart. And Seven Other Original Articles, Twenty Abstracts, Twelve Book Reviews. Cloth. Price, \$3. Pp. 368. Boston: Richard G. Badger.

This is a compilation of monographs, views and abstracts from the *Journal of Abnormal Psychology* for 1908, 1909 and 1910. Boris Sidis has a series of articles in an experimental study of sleep. Two articles on colored thinking by Fraser Harris are especially interesting, presenting a series of clinical reports on individuals who visualize figures, letters, days of the week, months, hours and other time and space conceptions in terms of color. Especially interesting to the reader of today are the personal impressions of Freud and his work by James J. Putnam. Most of the abstracts and practically all of the reviews are now out of date. The book would have been better suited for the average reader if the different articles on the same subject had been collected and printed as monographs rather than in the form of a bound volume of the *Journal of Abnormal Psychology*.

THE CHILD'S UNCONSCIOUS MIND: THE RELATIONS OF PSYCHOANALYSIS TO EDUCATION. A Book for Teachers and Parents. By Wilfred L. Fildes. Cloth. Price, \$2. Pp. 325. New York: Dodd, Mead & Co., 1919.

The title page states that his book is intended for teachers and parents. But it is also of absorbing interest to any one interested in mental development in the light of the newer psychology. How much of the present day speculation regarding the methods of mental growth will remain is difficult to say. That newer methods of study are substituting the clinical for the old speculative and philosophic method is in itself a promise of better things. In the introduction, Fildes discusses the point of view, concluding that the deeper knowledge of the nature of the individual, now for the first time available for teachers and parents, takes into consideration the workings of the unconscious mental activity, and that a knowledge of these processes as well as the order and manner in which they appear in the child development is an essential part of the training of all those who have to do with children. The influence and importance of unconscious desires and impulses, the interplay of the conscious and unconscious, the origin of specific thought in the unconscious mind, and the mechanism by which thoughts and impulses come into being are discussed clearly and

interestingly. The relation of the scientific method of study of the unconscious mind to medical research, and the fact that a modern psychology has developed almost entirely through the efforts of neurologists rather than the old school psychologists, are clearly shown. The blunders and shortcomings of present day educational methods, especially in the light of our recent acquired knowledge of mental processes, is made clear as well as the fundamental principles on which real education should be based. To those who have been following the development of knowledge in this field, the book will be a welcome addition. To others, it may come as a surprise, but it will be a beneficial one.

THE ADVENTURE OF LIFE. By Robert W. Mackenna, M.A., M.D. Cloth. Price, \$1.25. Pp. 233. New York: The Macmillan Company, 1919.

The author, a physician in the Medical Department of the British Army, endeavors to formulate a scientific interpretation of life. "Begun on a winter night in a little bell-tent in the north of France within sight of the firing line," it was written during the leisure moments of a busy medical officer's life in the midst of the closing year of the great war. Unable to accept the purely materialistic explanation of life, the author holds that the indomitable logic of facts drives one to the conclusion that behind all and above all there is an intelligent and beneficent Mind immanent in nature and in the life of man. The book is written in the hope that it may help to illumine the clouds of perplexity with which many an earnest seeker after the truth finds himself surrounded. The writer believes that the goal of nature is life, the aim of life is the development of intelligence, and the object of intelligence is a knowledge of God.

THE DISABLED SOLDIER. By Douglas C. McMorris, Director, Red Cross Institute for Crippled and Disabled Men. With an Introduction by Jeremiah Milbank, Vice Chairman, Committee of Direction, Red Cross Institute for Crippled and Disabled Men. Cloth. Price, \$2. Pp. 232, with illustrations. New York: The Macmillan Company, 1919.

This is an account of the methods used in rehabilitating disabled soldiers who after previous wars would have been condemned to a life of uselessness and pauperism. While much of this work is still in an experimental stage and it remains to be seen how much reconstruction is possible and what are the most effective methods to employ, yet any account of the plans being followed either in this country or abroad for the rehabilitation of crippled or disabled men is of interest. The material has been collected from the Red Cross, the Medical Departments of the Army and Navy, and military and civilian workers in this country and in Europe.

DIET LIST OF THE PRESBYTERIAN HOSPITAL, NEW YORK CITY. Compiled, with Notes, by Herbert S. Carter, A.M., M.D., Consulting Physician to the Lincoln Hospital. Second edition. Cloth. Price, \$1.25 net. Pp. 165. Philadelphia: W. B. Saunders Company, 1919.

This little book of diets contains an excellent and well-founded list, of particular value for institutions and men who know how to diet patients, but who are, perhaps, too busy to work out what to give them. It is to be regretted that Joslin's summary of Allen's treatment for diabetes is quoted from the early edition of his book and, therefore, omits Joslin's very important modification regarding the reduction of fat intake preliminary to fasting in certain groups of diabetics.

Infant Mortality.—The number of infants under 1 year of age per thousand born alive throughout the birth registration area as a whole was 93.8 in 1917, as against 101 in 1916 and 100 in 1915. This is equivalent to saying that in 1915 and 1916, of every ten infants born alive one died before reaching the age of 1 year, whereas in 1917 the corresponding ratio was a trifle more than 1 in 11. The rate for male infants in 1917, 103.7 per thousand living births, was nearly 25 per cent. greater than that for female infants, which was only 83.3. A minimum of 66.2 per thousand births is shown for infants with mothers born in Denmark, Norway, and Sweden, and a maximum of 172.6 for infants with mothers born in Poland, while for negro children the rate was 148.6.

Medicolegal

Location of Pesthouse by Board of Health

(*Birchard et al. v. Board of Health of City of Lansing et al. (Mich.)*, 169 N. W. R. 901)

The Supreme Court of Michigan reverses a decree that dismissed the bill filed in this case to restrain the maintenance in a residential district of a pesthouse or detention hospital for the treatment of infectious diseases. The court says that the question involved here was the protection of private rights by injunction against a public board authorized and required by the charter of the city to perform certain duties. The board of health was acting under charter provisions of the city, which not only authorized, but made it the duty of the board to locate and maintain such an institution; and it was the opinion of the trial judge that such provisions justified and authorized the board to select the site in question, and there maintain the institution in the absence of arbitrary action in so selecting it, which was not found to exist. There was much testimony tending to show that a pesthouse may be so conducted, and well-regulated ones are, as to cause no actual danger to nearby residents. But substantially all the experts who testified to this effect agreed that their opinion was not shared by the general public, and that the normal person has a horror and dread of a pesthouse, and a fear of infection from proximity to it. The court was not dealing with an emergency caused by an epidemic of an infectious disease. The detention hospital, or pesthouse, here involved, was permanent in character and the injury caused continuous. The court concludes that the provisions of the charter did not vest in the board of health the power to locate a pesthouse in a thickly settled residential district, where, by reason of its location, it would be a nuisance, and where its permanent maintenance would work continuing damage to adjoining and nearby property and would result in the destruction of the home in its comfort and well-being; and that the discretion lodged in the board was a discretion to be exercised by it in determining between different lawful locations.

Operating on Pregnant Woman for Supposed Tumor

(*Johns v. Pond (Calif.)*, 177 Pac. R. 293)

The District Court of Appeal of California, First District, Division 1, affirms a judgment against the defendant, a physician, for damages in an amount not stated, for having, as was alleged, negligently, and without occasion therefor, performed a surgical operation on the plaintiff, a married woman, 22 years old. The court says that the plaintiff alleged in her complaint that the defendant informed her that she had a fallopian tumor, and operated on her for its removal, when in fact the symptoms diagnosed as indicating the presence of a tumor were caused by pregnancy, and five months later she gave birth to a baby weighing 9½ pounds. She testified that when she first called the defendant she told him that she had been having severe pains in her back and head and also in the pelvic region, was having a scanty menstruation for almost a day each month, and informed him that another physician had said he thought she was pregnant five or six weeks. She further testified that at one time after the incision she heard the defendant make a statement, with reference to the operation, in which he said he had made a mistake, as to which last statement by her, and in some other respects, she was corroborated by other witnesses. The defendant testified that in addition to the symptoms related by the plaintiff she told him that she had been having hemorrhages between menstrual periods and suffered some dizziness; that she did not suspect pregnancy; that her condition was nothing like it had been with the first child; that considering the history of the case as related by her she was suffering from a fibroid tumor; that her condition was serious and required the performance of an operation; that the operation consisted of an incision about 2½ inches long, on making which he discovered that she was pregnant

and there was no condition of tumor, whereupon he concluded that she had given him an incorrect history of the case, sewed up, dressed, and banded the incision. According to the testimony of several medical witnesses produced by the plaintiff, based on the history of the case as claimed by her to have been furnished to the defendant, he should have kept her under observation for at least six weeks before operating, when he would have discovered the error in his diagnosis. According to the testimony of nine experts called for the defendant, he was justified in making an immediate operation for tumor only in the event of the presence of hemorrhages between regular menstrual periods; otherwise he should have kept the patient under observation and awaited developments.

From a résumé of the evidence, the court thinks it quite clear that, if the jury believed, as it appeared it did, the testimony of the plaintiff as to what she told the defendant relating to the history of her case, then the operation was unnecessary, and the verdict in her favor could not be disturbed.

The plaintiff having closed her case without introducing any expert evidence, the defendant moved for a nonsuit, arguing that the mere statement by him to the plaintiff and her mother that he had made a mistake in diagnosing the plaintiff's case as one of tumor rather than pregnancy was not sufficient to establish negligence, in the absence of testimony that such incorrect diagnosis was arrived at by reason of negligence. Assuming this to be true, it was sufficient that evidence was introduced later in the case which tended to supply this defect, it not appearing that the defendant was prejudiced thereby.

The court committed no error in refusing the defendant's requested instruction that, if there is more than one method of treatment recognized by the medical profession, a physician may adopt either, for the reason that the instruction was substantially given when the court told the jury that if the defendant applied reasonable skill and judgment with ordinary care, he was not liable for any damages or injuries consequent on an honest mistake or error in making a diagnosis, in prescribing treatment, or in determining on an operation; and if what he did appeared to be in accordance with recognized authority and good current practice, a verdict must be found for him. Rehearing denied by supreme court.

Full Release to Employer Available to Physician

(*Hogman v. Reese (Wisc.)*, 170 N. W. 282)

The Supreme Court of Wisconsin, in this action for alleged malpractice, reverses an order that sustained a demurrer by the plaintiff to the defendant's answer setting up as a defense that the plaintiff, in consideration of \$3,000 paid to him by his employer, had given the latter a release in full satisfaction and discharge of all claims, accrued or to accrue, in respect to all injuries or injurious results, direct or indirect, arising or to arise from the accident which he had suffered. The court says that it was insisted by counsel for the plaintiff that it appeared from the facts pleaded in defense and demurred to that two separate torts or wrongs were committed, and that settlement for one did not settle the other, and that the principle of release of joint tortfeasors or wrongdoers did not apply. But the rule invoked did not apply in this case. Whether the master and the physician were in a technical sense joint tortfeasors was not material here, because it was clear on the allegations of the answer that all damages sustained by the acts of the master and the defendant physician were settled for and satisfied. The malpractice, if any, contributed to produce the injury settled for and satisfied by the master; hence such cause of action against the defendant was compensated for and extinguished by the settlement made. Clearly the settlement covered all damages sustained, including injury caused by the alleged malpractice. The damages sustained by the acts of the defendant concurred or were connected with the negligence of the master in producing the injury and damages settled for by the master. The receipt given by the plaintiff, which was not questioned, was broad, and showed full settlement for injuries received through the negligence

of the master, as well as on account of the alleged malpractice of the defendant. The alleged wrong on the defendant on treating the injury contributed in large part to the injury sustained by the plaintiff. The injury caused by the malpractice would not have occurred but for the original injury, and resulted because of such injury, and was a proximate result thereof. The plaintiff, having been paid for all damages which he sustained, had no cause of action against the defendant physician for the same claim or any part of it.

Society Proceedings

AMERICAN PEDIATRIC SOCIETY

Thirty First Annual Meeting, held in Atlantic City, N. J., June 16-18, 1919

(Continued from page 140)

Certain Aspects of Cutaneous Hypersensitiveness

Dr. E. C. FLEISCHNER, San Francisco: Experimental proof demonstrates that cutaneous hypersensitiveness is not present in sensitized uninfected guinea-pigs. A study of cutaneous hypersensitiveness in the chronic diseases of guinea-pigs, including tuberculosis, abortion disease, rodent paratyphoid and undulant Malta fever, indicates that cutaneous hypersensitiveness is always an indication of the presence of a focus of infection. We find no evidence of its being an indication of immunity. We have been able to demonstrate the similarity of *B. melitensis* infection and that of *B. abortus* in guinea-pigs, the evidence being based on pathogenicity, apparently identical microscopic findings and gross changes involving the viscera, cutaneous hypersensitiveness, and some evidence of a positive serologic relationship. We have never been able to demonstrate that hypersensitiveness was developed in the offspring. Dr. Theobald Smith has looked over the microscopic specimens, and states that the lesions in the spleen, lymph nodes, and liver of animals infected with *B. melitensis* are absolutely indistinguishable from those of abortion disease.

Quarantine and Disinfection in Scarlet Fever

Dr. J. CLAXTON GIDDINGS, Philadelphia: In U. S. Army General Hospital No. 9 it was possible to secure absolute lack of contact between patients and the healthy, except in the inevitable instances in which orders were not obeyed. In one case that developed in an attendant, the agency of an infected blanket was strongly suggested. A uniform minimum length of quarantine of forty-two days from the day of entry into the camp hospital was enforced. On the fortieth day, each patient was carefully examined. All those who showed any evidence of abnormality in the throat, nose or ears were inspected by the nose and throat specialist, who decided whether or not the patients gave any evidence of being potential carriers of the disease. At the end of the quarantine period, 59 per cent. of the patients were ready for discharge; 41 per cent. required more or less treatment. At the conclusion of quarantine, each patient was given an eribodex bath, shampoo and change of clothing, and was then transferred to a clean ward in another part of the building. All soiled linen was soaked in a 2 per cent. solution of cresol for two hours or longer before being sent to the laundry. Shoes, hats and leather belts were exposed to formaldehyd in sealed closets for twenty-four hours. Blankets and woolen clothing were sterilized in the autoclave. The floors of the wards and halls were mopped freely with a 2 per cent. solution of cresol, and all flat surfaces were wiped with the same solution. Mattresses and pillows were aired for three days with all windows open. Within two weeks the wards were again occupied, and there were no further cases of scarlet fever for a period of nearly a year. Until the infecting organism of scarlet fever is demonstrated, the proper length of quarantine always will be open to argument. In accounting for the spread of this disease, the chronic carrier would seem to be the most likely agent. *A priori*, the unhealthy nasopharynx and throat may be under

the suspicion of harboring the infection. Examination by a throat specialist may enable us to prevent the discharge of the potential carrier and possibly to hasten the discharge of the healthy person. In mild cases with healthy throats, thirty-five days or less may cover the danger period. It is much better to err on the side of safety than to run the risk of a premature discharge. The factor of the human carrier in the etiology of contagious disease is being accepted to such extent as to make it extremely questionable whether any measure other than thorough cleansing is necessary after infection. Formaldehyd in proper concentration and with sufficient moisture probably will destroy the organism of scarlet fever; that this optimum result is obtained is extremely doubtful. Disinfection of linen and woollens and disinfection and removal of the dust which accumulates on floors and furniture, followed by thorough sunning and airing, appear to be the actual requirements for safety.

DISCUSSION

DR. D. J. MILTON MILLER, Atlantic City, N. J.: There are those who believe that the desquamation from the epidermis in scarlet fever is not contagious, and if that is the case what is to be our belief in reference to quarantine? When desquamation continues indefinitely, of course, we cannot continue to keep the patient in quarantine indefinitely; on the other hand, catarrhal symptoms often disappear in a mild case after the acute stage of the disease is past, so that the duration of catarrhal symptoms cannot serve as a guide to the period of quarantine. Until we have more definite information, desquamation should continue to determine the period of quarantine, and quarantine should be continued until desquamation is complete.

DR. J. P. CROZER GRIFFITH, Philadelphia: I do not think that desquamation is a criterion as to the period of time during which scarlet fever is contagious. I can cite a number of instances in which it had continued for a longer period than forty-two days. It must also be remembered that there are other skin diseases besides scarlet fever in which desquamation may occur, and such diseases may exist coincidentally with scarlet fever.

DR. HENRY HEIMAN, New York: I am glad we are getting away from the superstition that scarlet fever is carried by clothing. To acquire the disease one must come in contact with a person who has the disease or with a carrier. The disease is conveyed more easily by a person ill with the infection than by a healthy carrier of the disease.

DR. J. H. MASON KNOX, Baltimore: I should like to ask if any one has data to show how long scarlet fever patients continue to have sore throats. The sore throat appears before the eruption, and I have seen epidemics started by early cases before the eruption appeared. Where there is any suspicion of the possibility of scarlet fever, it is more important to isolate the patient early in the course of the disease than later.

DR. J. C. GITTINGS, Philadelphia: While thirty days' quarantine in scarlet fever may perhaps be sufficient, six weeks was required in the camps. If a child or a susceptible person is likely to come into contact with a person just convalescent from scarlet fever, it is better to err on the side of safety and maintain quarantine for six weeks.

Cholesterol Metabolism of Infants

DRS. K. D. BLACKMAN and J. L. GAMMEL, Baltimore: Cholesterol, which is an important constituent of tissue cells, may also bear important relations to certain physiologic processes. Cholesterol or substances nearly identical with it are present in all natural foods. If cholesterol is not synthesized in the body, an adequate amount must be provided in the food in order to maintain the chemical structure of the tissue cells and provide for growth. In the food of an infant the amount of cholesterol is roughly proportional to the amount of fat present. No coprosterol was detected in the stools of infants. Apparently none of the cholesterol excreted by the infant underwent reduction in the intestinal tract. This fact made it possible to study the cholesterol balance in infants. It was assumed that the finding of a consistently negative cholesterol balance in normal gaining

infants would indicate cholesterol synthesis. In order to determine with accuracy the cholesterol content of milk and stools, it had been necessary to modify considerably an existing colorimetric method. The cholesterol balance of several infants has been determined. With one exception, a large negative balance was found. The results so far obtained suggest that cholesterol is synthesized within the body. The relation of cholesterol to maintenance and growth apparently do not depend on the amount of cholesterol in the food.

Certain Nutritional Disorders in Infants Associated with a Proteolytic Intestinal Flora

DR. LANGLEY PORTER, San Francisco: Investigation of many stools evacuated by healthy infants and children showed that there is a standard flora in the intestines of healthy babies and children. Examination of stools of children suffering from different types of nutritional disorders demonstrated that in such cases the flora in the intestine departed from the normal. The normal stool showed a flora composed almost equally of aciduric and protein-splitting organisms. In the nutritional disorders studied, the flora all showed a predominance of proteolytic types of bacteria. These children all showed clinical disturbances evidenced by symptoms of toxemia. They all responded to limitation of milk, meat and egg white, together with a diet high in lactose and dextrins, by a swing of the intestinal flora to a predominance of preventive forms. Coincidentally with this change there was an amelioration of the clinical symptoms. On a rational diet, well-being has been maintained and the stools have remained at a floral balance approaching the normal. No claim is made to having established an etiologic relationship between alimentary intoxications and the flora of the intestine, but our investigations point to the possibility of such a relationship, and to the need of further and more intensive investigation.

DISCUSSION

DR. HENRY KOPLIK, New York: Without wishing to criticize the milk which Dr. Porter used, I wish to point out that a great deal depends on how protein milk is made. Unless it is made properly it rather hurts the baby and may cause bloody diarrhea. Finkelstein realized how important it was to have the milk properly prepared, and he installed his own apparatus. Again, milk may be stored too long before being prepared, and here we are in the hands of the purveyors of milk. In cases such as Dr. Porter described I have been accustomed to eliminate the sugar from the diet. Dr. Porter gave lemonade, while I eliminate all sour foods. However, Dr. Koplik has obtained good results by following his method, and I obtain good results with mine.

DR. E. C. FLEISCHNER, San Francisco: Any method which offers us some criterion on which to base feeding of the type of infants Dr. Porter described is acceptable. It is better to have a method based on a logical foundation than to proceed in an empiric way. Where butyric acid fermentation is concerned it is better to leave the fat out of the diet, and I think that is the method Dr. Porter has followed. If the etiologic factor is the proteolytic anaerobes, as it frequently is, then to get at the root of the evil the protein element must be considered and both fats and proteins must be reduced or eliminated, at least temporarily. Dr. Porter has offered us a tangible basis on which to feed this type of patients.

DR. LANGLEY PORTER, San Francisco: Any one who has studied the subject must have been struck by the fact that we cannot feed high fats when the protein is low, as is shown by the soapy stools that resulted when we followed this method; that was the reason Finkelstein resorted to the albumin milk.

Transfusion in Infants and Children

DR. HENRY KOPLIK, New York: Transfusion in the newborn is applicable in (1) cases of uncontrollable hemorrhage from wounds, umbilicus or scalp hematoma; (2) forms of frank melena with hemorrhage from the intestine and subacute or gastric hemorrhages; (3) concealed melena in which the outward objective signs of hemorrhage are slight, such as occasional ecchymosis on the surface but in which the evidence of internal hemorrhage is great, and (4) cases of

severe and continued hemorrhage in the new-born from surgical wounds, such as circumcision. There are before us two methods of transfusion from which to choose, and the time is scarcely ripe to decide in favor of either. These methods are the Unger and syringe method (Lindemann) and the so-called citrate method (Lewishohn). I have used both methods and found them applicable. Cases have come under my observation in which the subcutaneous injection of serum had absolutely failed to control hemorrhage, or even the subcutaneous introduction of whole blood. In these cases, a single definite transfusion succeeded in combating symptoms which the serum and subcutaneous injection of blood failed to control. Temperature elevation is not a contraindication to transfusion, nor is congenital syphilis. In hemophilia in late infancy and childhood, transfusion was uniformly successful in combating the hemorrhages even when large amounts of blood had been lost. In a case of pernicious anemia, a very rare condition in childhood, two transfusions of 140 and 120 c.c. of citrated blood initiated an improvement, and the child went on to recovery. Transfusion is useful in acute diseases with a tendency to hemorrhage. Acute and chronic leukemia are not benefited permanently by transfusion, and purpuric conditions of all varieties are not improved by transfusion. Henoch's purpura is particularly rebellious to treatment. In several patients who had a low temperature with endocarditis crises due to an infectious endocarditis, transfusion was employed without success. There was one form of streptococcus invasion which if transfused intensively and repeatedly might improve after the introduction of new blood, and this was the form of blood sepsis which did not affect the heart itself. In certain septic infections it was advisable to remove blood in order to make way for the introduction of new blood. In a case of influenza nephritis I employed blood transfusion when the patient was sinking fast and the urine showed the presence of blood. Not only did the transfusion of blood in this case cause a cessation of the bleeding, but there was complete recovery from the nephritis. On the other hand, many patients with the same affection were transfused without success, possibly because the physician waited too long. There should be a definite idea or indication for the performance of transfusion, since its indiscriminate use may bring the whole method into disrepute.

Postinfluenzal Encephalitis

DR. HENRY HEIMAN, New York: From a study of the relations of this condition to influenza, I am of the opinion that the most appropriate designation is "postinfluenzal encephalitis." We have been able to differentiate three main forms depending on the severity and the most prominent symptoms. These may be grouped into (1) irritable, (2) lethargic and (3) lethargic with paralysis. The irritable type is characterized by marked restlessness, excitability, and almost continuous crying. In the lethargic type, as the name implies, the most prevalent feature is a drowsy state. The facial features are expressionless, resembling the Parkinson syndrome. There may be convulsions or twitching of the face muscles. There is frequently moderate rigidity of the neck. Most of the cases fall into the third group of lethargy with paralysis. In this type we find, in addition to the stuporous state, some form of paralysis and frequently convulsions. There may be an involvement of the extremities or cranial nerve palsies. All of these cases gave a history of previous influenzal infection. In one child the nervous syndrome followed immediately, and in another as long as four months had elapsed. The average was about two weeks. Convulsions were the first manifestation in three cases, stupor in four. Drowsiness and stupor continued as prominent symptoms throughout the course of the disease. Fever played a small part in all the cases. The fundi were examined in all these cases, but showed nothing characteristic. Of eight specimens of cerebrospinal fluid, only one showed definite changes. There were 80 cells per cubic centimeter, albumin was present, and there was a definite reaction to Fehling's solution. There were no uniform changes in the blood picture. The prognosis was better than the alarming state of the patient would indicate. There was no specific therapy.

In the irritable type, mixed bromids and chloral were of some value. Lumbar puncture had not proved of special benefit.

DISCUSSION

DR. HENRY KOPLIK, New York: We all saw cases of this kind throughout the epidemic of influenza in New York. These cases were quite similar to the cases of poliomyelitis that have been described on both sides of the Atlantic. They appear to be of the hemorrhagic type affecting the brain and not the cord. There are ophthalmoplegia, facial paralysis, a rigid neck, and Macewen's and Kernig's signs, all being quite marked. The lethargic cases may resemble tuberculous meningitis, and some physicians have made the diagnosis of tuberculous meningitis to find that at the end of a week or ten days the patients were on the road to recovery. We have performed lumbar puncture in some cases of this type, but find that the patients do well without resorting to this procedure. There were different types of encephalitis following influenza; not all were of the lethargic type.

DR. I. A. AET, Chicago: Not all the cases of encephalitis which we have been seeing are necessarily due to influenza. Encephalitis may follow pneumonia, typhoid or whooping cough. Encephalitis includes a group of diseases. The disease has a selectivity for certain portions of the brain. In a number of cases the anterior motor areas were affected, and in some there is a one-sided paralysis. The prognosis is good so far as life is concerned, but a number of those affected remain paralyzed.

DR. RICHARD M. SMITH, Boston: In one case of encephalitis in a child 4½ months old, all the symptoms mentioned were present, and in addition the child was still unable to cry after the condition had lasted a week.

DR. FRITZ B. TALBOT, Boston: Have you had any reports from adults as to whether double vision was among the early symptoms in encephalitis following influenza?

DR. HENRY HEIMAN, New York: I have not seen diplopia, but I have seen ophthalmoplegia.

Cause of a Sporadic Case of Cerebrospinal Meningitis

DR. HENRY L. K. SHAW, Albany, N. Y.: An infant on a farm developed cerebrospinal meningitis. There was no record of any previous cases in this locality, and the case was definitely traced to a soldier who had visited the home and fondled the child, January 28. The soldier said that to his knowledge he had never seen or been in contact with, or known of a case of meningitis in his regiment. He was found to be a meningococcus carrier. Nasal cultures from all other persons who visited the farm were negative. June 10, the organism still persisted, though the man had been under treatment and had used irrigations of all kinds.

As the disposition of carriers is very largely a public health measure, a questionnaire was sent to the various state departments of health in order to ascertain their mode of procedure regarding carriers of meningitis. The answers revealed very little uniformity in the isolation of patients and in dealing with carriers. There were no provisions for the detection of healthy carriers and the compulsory bacteriologic examination of contacts. Public health legislation on this subject is imperative if we are going to limit the spread of communicable disease. It is the duty of the pediatrician to keep abreast of public health progress and to assist in educating our communities in the new order of things.

DISCUSSION

DR. FRITZ B. TALBOT, Boston: Dr. Shaw's report is important and timely, and serves to bring out the susceptibility of the young. The practice in the army in Europe when they found a carrier was to send him to a place where there was below a certain number of carriers, and in that way they diluted the quantity of infection. If the infection was sufficiently diluted, an epidemic did not result. Dr. Shaw's case is very suggestive of what would happen if that plan were tried in civil life.

DR. L. EMMETT HOLT, New York: I can cite a case which parallels Dr. Shaw's. In this instance the husband, who brought the disease to his wife, was advised to take a long

sea voyage. He was gone several months, but when he returned he was still a carrier of the disease. After treatment by a skilled nose and throat specialist, he was freed from the organisms. It is important that we recognize the fact that thousands of returned soldiers are distributed through the community and that undoubtedly a number of them are carriers of disease, and as a consequence we are likely to see many of these cases cropping up.

DR. HENRY KOPLIK, New York: I also have observed an instance almost exactly like that described by Dr. Shaw.

DR. HENRY HEIMAN, New York: A case has been reported of a child, 6 weeks old, that had never left home and was in the hands of a nurse, but nevertheless contracted meningitis and died. It is our practice to make two nose and throat cultures of those who have come in contact with cases of cerebrospinal meningitis, so that we can label the carriers. That is about as much as we can do for them, as it is very difficult to get rid of the organisms. My attention has recently been drawn to another condition that is being brought back by the soldiers, and that is trench mouth.

AMERICAN SURGICAL ASSOCIATION

Fortieth Annual Meeting, held at Atlantic City, N. J., June 16-18, 1919

The President, DR. LEWIS S. PILCHER, in the Chair

General Considerations as to the Treatment of War Wounds

DR. ANTOINE DEPAGE, Brussels, Belgium: The majority of war wounds are infected or, at least, contaminated. In consequence of this, débridement became a formal indication of the first rank. Our procedure is as follows: On admission of the patient, the injured region is shaved, and then washed with a neutral solution of sodium oleate. Débridement and épluchage of the wound are practiced immediately thereafter. At the same time the Carrel tubes are introduced to the bottom of the wound so as to permit the irrigation of the entire wound surface. To the entire surroundings of the wound are applied compresses smeared with petrolatum in order to prevent irritation of the skin. The wound is dressed with compresses of absorbent material. After the return of the patient to bed, the Carrel tubes are connected with the receptacle containing the surgical solution of chlorinated soda, and irrigation is carried on every two hours, controlled by a simple pressure forceps of Mohr. The dressings are renewed every day, careful lavage of the wound being made with sodium oleate. One must not allow the slightest concretion to remain on the skin about the wound lest colonies of microbes be hidden. We were not able, however, to derive from the Carrel method all its benefits until we made a regular determination of the abundance of the micro-organisms in the wound exudates. This bacteriologic control was repeated in the same wound every two days, and tracings were made of the microbic strength. Infected wounds were rendered sterile by the Carrel treatment in from six to eight days. Bacteriologic evolutions in a wound may be considered under the three periods of acute infection, attenuated infection and sterilization. These periods correspond to three periods in the organic reaction of tissues. In deciding the moment of suture we have recognized that: (1) wounds slightly infected by ordinary microbes may be sutured with every chance of success; (2) the presence of staphylococci does not contraindicate suture; (3) the perforating organism remains enclosed in the wounds only a very short time, but until these microbes disappear it is dangerous to suture; (4) a wound should not be sutured in the presence of even a slight streptococci infection.

To determine better the moment most favorable for suture, we have supplemented the counting of the microbes on the smears subjected to bacteriologic examination by cultures instituted regularly after débridement and before the suture, and conclude that: (a) For wounds feebly infected from the first day with ordinary microbes we may proceed to suture

when at the second examination the smear yields only one microbe in a visual field. (b) For wounds strongly infected by ordinary microbes, we may resort to suture from the moment the curve comes down to one microbe in four fields. (c) For streptococci infection we should never suture, but submit the wound to adequate treatment, preferably that of Carrel, and wait until the streptococci have disappeared, or become sufficiently attenuated to permit primary union. Streptococci vaccination may here render the greatest service. Immediate primary suture may be made immediately after débridement or from two to four days after débridement. Delayed primary suture or early secondary suture is done without refreshing wound surfaces, by simply approximating them. The suture may be made in the course of the granulation of the wound when sterilization is assured. Secondary suture always necessitates the refreshing of the wound surfaces. The objective toward which we direct the surgical treatment of open fractures, apart from the orthopedic treatment, is the transformation of an open fracture into a closed fracture. In joint wounds our results show the superiority of immediate suture after wide arthrotomy, closing of the joint cavity, over any other method of treatment. In wounds of the elbow and shoulder, however, the Carrel treatment followed by secondary suture or by cicatrization by second intention is evidently indicated.

Most Important Factor in Treatment of War Wounds in Civilian Surgery

DR. GEORGE W. CRILE, Cleveland: After four years of intensive study, from the conflict of views regarding the treatment of war wounds, there is emerging a universal recognition of the one agent of successful military surgery—the good surgeon. Thus, our vast experience in traumatic surgery has taught us the same lesson we had already learned in civil surgery, that sound surgery only will bring success. The good surgeon considers the wound as well as the patient; respects the tissues of the anesthetized man as well as of the unanesthetized man; heeds all the defenses and reparative forces of the patient, and is the exponent of no single method, but adapts his methods to the military situation, the possibilities of after-care, the type of transport—seeing clearly the tomorrow of the wound and weighing accurately his chance for success.

Problem of the "Slightly Wounded" in Military and in Civilian Practice

DR. WILLIAM E. LOWER, Cleveland: The great war supplied to medical officers a postgraduate course in organization, transportation, sanitation, hospital construction, management of supplies, treatment of every kind of wound by every variety of method, and in noting what not to do. One of the problems was that presented by the slightly wounded man, the "walking wounded." The tendency in rush periods to leave the slightly wounded to the attention of the less trained men proved a dangerous hazard to the man power of the army and the time factor in the return to the line became of supreme importance. The problem is of equal importance in civilian practice. This is especially true in the smaller manufacturing plants; the larger industries appreciate the value of the time loss of their employees. Many of our hospitals also refer to inexperienced operators the cases of minor injuries. We are all familiar with serious results following inept treatment of minor conditions, both in accident work and in the operating theater. The economic loss of time, as well as the too frequent performance of these minor operations under untrained anesthetists, has been too long endured. This association should call attention to the need of proper organization to assure better care for the lesser as well as for the greater injuries, to the minor as well as to the major operations.

What Would Be the Benefit to the Civilian Surgeon of the Experience Gained by Our Military Surgeons in the Recent World War?

DR. EDGAR A. VANDER VEER, Albany, N. Y.: Early in the war the attempt at aseptic technic broke down, fully 85 per cent. of the wounds having suppurated and there being very

many cases of tetanus. The system of treatment of fractures by the allied surgeons revealed great confusion. In the treatment of wounds, army surgeons were obliged to return to antiseptic methods, and the experiments in this direction led some of the British surgeons almost entirely to abandon the use of strong germicidal solutions, finding that sterile water alone kept the wounds in satisfactory condition for healing. While the Carrel-Dakin method accomplished much, it is an expensive, painful and somewhat protracted line of treatment. The antiseptic treatment was employed, however, to a great extent in the third and fourth years of the war. It has been demonstrated that wounds must be handled with great care, and dressed sufficiently often, but not too frequently and with a minimum of distress. An excellent system of transportation was developed, and the short history accompanying the patient has saved much suffering. The standardization of splints in the treatment of fractures has been of great benefit, and their proper application, with the use of tetanus antitoxin has lowered the mortality. I believe that ether and chloroform will continue to be our most reliable anesthetics.

No Flap or Gailloine Amputation: An Unfortunate Resurrection

DR. JOHN H. GIBBON, Philadelphia: Because of the frequent secondary hemorrhages, the slow healing extending over months, the painful dressings and the numerous secondary operations after the no flap amputation, this method is designated an unfortunate resurrection. The reflected skin flap amputation obviates these complications. The additional time required for making the reflections of the flap occupies only a few minutes and cannot add to the shock. As soon as the wound has become clean, the flaps are ready to cover it; whereas, in the flapless method a second operation or the employment for a number of weeks of some appliance to draw down the skin is necessary, and these in many instances fail. One reason for doing the no flap operation is that it gives a good stump for the wearing of an artificial limb. It is my belief that the reflected skin flap amputation gives exactly the same kind of stump, but gives it earlier and with less pain and less danger. If this is not so, the guilloine must then be employed in civil practice, which procedure I doubt any one would be willing to inaugurate.

DISCUSSION

DR. JOHN H. GIBBON, Philadelphia: I want to express the obligation which I think every surgeon who has worked in France owes to Dr. Depage. We owe to him more than to any other man what we were able to accomplish in the treatment of war wounds. I have seen no benefit from blood transfusion in acute infection. I have seen transfusion done a number of times in men badly shocked. They would be braced up for three or four hours and then die. I am speaking particularly of men in the advanced hospitals. With reference to the individual reaction of the patient to infection, I saw many wounded in Belgium under the worst conditions of winter, and I saw many wounded in a much pleasanter part of the world in the spring and summer and fall of the next year, and I cannot say that I observed any decided difference in the reaction of the individual patients to infection. While we have been taught that in the treatment of wounds the first operation should be thorough and complete, I do not believe that the use of antiseptics can be eliminated in the sterilization of infected wounds.

DR. THOMAS W. HEXTINGTON, San Francisco: I want to emphasize the value of the trained nurse in war surgery. In Italy, where it was first thought that the trained woman nurse could not be placed in hospitals, it came to be the opinion of those in authority that they were helpless without her.

DR. ALEXIS V. MOSCOWITZ, New York: In the treatment of wounds the question is not between surgery and the Carrel-Dakin treatment because you all know that the Carrel-Dakin treatment will never take the place of good surgery. It is, however, of wonderful assistance in the treatment of infected wounds. If of these two agencies I could have but one, it would be good surgery by all means; but if I could have good surgery with the Carrel-Dakin treatment, I should feel well equipped.

DR. HENRY H. M. LYLE, New York: We should emphasize the fact that the general employment of nitrous oxide is dangerous, except in the hands of men experienced in its use.

DR. GEORGE E. BREWSTER, New York: The most important occurrence during the war in the treatment of shock was the organization of the shock team. This consisted of two men expert in the treatment of shock cases, from two to four nurses and the same number of orderlies. Appliances for blood transfusion and other means of stimulation were provided. The teams were installed in every front area hospital, and so far as I know continued until the end of the war.

DR. HOWARD LILIENTHAL, New York: My experience in transfusion in the front area differs from that of Dr. Gibbon in that when a patient had come in who had lost blood no matter whether or not he was septic, the most powerful influence for his good was the replacement of that blood. There is no doubt about it; it is a matter of mathematics. As to the sepsis, you do not know when you get a septic man how much blood may have been lost before he reaches you. It is my opinion that there is nothing quite so good in profound anemia with sepsis as blood transfusion.

DR. A. P. C. ASHFURST, Philadelphia: Dr. Depage pointed out in 1915 that if in the first six hours the red blood count fell below 4,000,000, practically all the wounded died unless transfused. It is well to remember war surgery and to learn the full truth about it.

Treatment of Recent Wounds of Knee Joint

DRS. EUGENE H. POOL, New York, and JOHN H. JOHNSON, Philadelphia: The principles of treatment may be summarized as follows: Complete debridement of the tract of the projectile through the soft parts and bone; removal of foreign bodies; thorough irrigation of the joint; distention of the joint with ether; absolute closure of the joint by suture; primary or delayed closure of the superficial parts according to the rules laid down for primary suture of the soft parts alone; finally, early active motion. In extensive involvement of the articular surfaces an effort should be made to save the joint, provided the conservable articular surfaces and soft parts are sufficient to warrant the hope of a useful joint. It must be remembered that stability in the knee is essential. When the joint cannot be saved, the question of extensive resection and amputation must be weighed carefully. Early active mobilization is the rule. With suspicion of infection, aspiration should be done at once and a culture made. In suppurative arthritis the important feature is early drainage, which is best instituted by lateral incisions well back, though occasionally an incision elsewhere may be employed. No drains should be used. Splints are dispensed with or arranged for support without joint fixation. Free mobility every two hours so that the active movements evacuate the joint should be enforced. Early, noninfectious infections with little or no bone involvement usually do well.

The Willems Treatment in Knee Joint War Injuries

DR. CLARENCE A. McWILLIAMS, New York, and DR. WILLIAM B. HETZELL, Pittsburgh: The plan is made that the old immobilization treatment be discarded for the Willems immediate, continuous, active mobilization procedure. In thirty-two of eighty-two cases no fracture was present; in eight there were simple fractures, while in the remaining forty there were combinations of comminuted fractures, eighteen of the patellae, twenty-nine of the femora, twelve of the tibiae and one of the fibula. Fifty-seven cases, or 78 per cent., remained clean. In seventy of seventy-six cases the synovial membrane was completely closed, while in twenty-six the external tissues leading down to the closed capsules were left open. In six only were the joints drained. In thirty-six of the clean cases, only nine patients had perfect function finally; three joints were ankylosed, while in twenty-four there were varying degrees of motion. Of these seventy-three cases, sixteen became infected, of which four finally became ankylosed; one joint was resected, three patients had amputations; four died of the infections; one had flexion of 90 degrees, while the results in three cases are unknown. Compared with these methods of resection or immobilization, Willems gives the following statistics in the

final outcome of 100 consecutive knee cases, 18 of which became infected. There were no deaths and no amputations; there were one resection and two stiff joints.

Transthoracic Laparotomy

DR. WILLY MEYER, New York: In cases of injury, operating by way of the chest to reach organs in the vault of the diaphragm, it has been found best to attend first to the damage wrought in the chest and then try to reach and deal with the injured abdominal organs by a transthoracic laparotomy, either by deliberately incising the diaphragm or by enlarging the wound in it. Sauerbruch reports three operations successful, in all of which a differential air pressure apparatus was employed. He lays stress on the importance of incising the diaphragm transversely or obliquely to the direction of its fibers, not parallel, in order to avoid injury to the phrenic nerve. From my own experience and from the literature I believe that bullets in thoracic as well as abdominal organs are probably best removed; that the question of whether operation should be done immediately after the accident or later depends on the seriousness of the concomitant symptoms, and that simultaneous injuries to chest and abdomen, as also injuries to the convexity of the liver or the spleen, without previous penetration of the chest, if not accessible from below, render the indication for transthoracic laparotomy. Involvement of intra-abdominal organs can be determined before or during thoracotomy. These operations are best done with the help of some differential pressure apparatus. I further believe airtight and watertight drainage of the chest (Kenyon's) to be the safest procedure for the after-treatment.

Treatment of Gunshot Wounds of Chest

DR. ELLSWORTH ELIOT, JR., New York: The treatment of gunshot wounds of the chest is either conservative or radical; the former is almost always the rule in civil practice; the latter is occasionally justifiable for overcoming infection, especially in the chest wall. It should be emphasized that this dreadful complication becomes less frequent as the lung is approached and is uncommon in wounds of that viscus, even in the presence of hematoma or hemothorax. Whether this is due to the removal of foreign and infectious material from the surface of the projectile as it passes through the chest wall or to the inherent greater resistance of the lung to certain forms of pyogenic infection, or to both factors, is yet to be decided. The result of secondary operation, should infection develop, is much more favorable because of the improvement in the general condition of the patient and the fact that formation of adhesions has limited infection to a segment of the pleural cavity, thereby greatly diminishing the operative risk.

DISCUSSION

DR. HOWARD LILIENTHAL, New York: A developing pneumonia of the opposite lung has been the cause of very bad statistics in gunshot wounds of the chest. Such a pneumonia will come on whether you operate or not. I have seen fatal pneumonia after a perforating machine gun bullet wound in which nothing could be found to kill the patient except the pneumonia of the opposite lung. In making the aspiration I use instead of a needle a fine trocar and cannula to which a rubber bag is attached so that the fluid will siphon out. To prevent a pneumothorax it is only necessary to have the patient, after you have finished the aspiration, by expiration force the lung into contact with the pleura while you have the other end of the tube under water. If at the cessation of the expiration the cannula is withdrawn, the roentgen ray will show little or no pneumothorax whatever, the lung being in absolute contact with the chest wall.

DR. ELLSWORTH ELIOT, JR., New York: It was for the prevention of the high mortality in gunshot wounds of the chest that the conservative procedure was followed in every instance, and in no instance during the entire campaign in the evacuation hospital was exploration of the chest made. Our results by the conservative treatment were so uniformly good that we did not regard the radical treatment necessary or advisable.

Precipitin Reaction in Infant Stools.—The technic in the work reported by Hektoen and Grulee was the same as that used by Hektoen, Fantus and Portis, except that tests were made with both antihuman and antibeef serum. One hundred and thirty-three stools of thirty-four newly born infants were examined. Of these, thirty-two stools from nineteen infants gave positive reactions to antihuman serum; two were positive to antibeef serum and one was questionably positive. All stools were examined with both antibeef and antihuman serum. Of the positive reaction to antibeef serum, in the two instances in with a reaction to antibeef serum occurred, and also in one doubtful case, there was no record of cow's milk having been given. The examination in the case of older infants was carried out on 407 stools from forty-eight different infants, varying in age from 5 days to 22 months. Here the reaction to antihuman serum was positive in 115 stools, and to antibeef serum in sixty-three stools. In only fourteen stools were both reactions positive. The tests were made in cases without selection. The infants were fed on albumin milk and mixtures of cow's milk in which the percentage of protein was rather high. In a careful survey of the cases the authors were unable to determine any connection between the type or frequency of stool or the character of the food and the reaction in the stool. The work is being continued with particular reference to tests for casein and also other substances.

Bacillus Tuberculosis in Tonsils of Children Clinically Nontuberculous.—The excised tonsils from forty-five children were examined by Austin for the presence of tuberculosis by means of the inoculation test on guinea-pigs, histologic examination of sections, cultures on Dorsett egg medium and direct smears. In all cases the histologic examinations showed no evidence of tuberculosis, and no tubercle bacilli were demonstrated in any of the cultures or direct smears. The inoculation test yielded a positive result for tuberculosis in only one of the forty-five cases. The bacillus was of the human type. The child was 4 years of age; the father and mother were living and well; there was no evidence of tuberculosis in the past history of the child; a previous admission to the hospital had been for feeding. Otitis and enteritis had developed, but no tuberculosis had been detected and a von Pirquet test had been negative. At the time of removal of the tonsils the child was well developed and well nourished, and had no palpable cervical lymph nodes. The children in this series came from a community where the supply of cow's milk was far less likely to be contaminated with the tubercle bacillus. Furthermore, but two children in the group were from families in which there were cases of tuberculosis, and none of the children gave clinical evidence of tuberculosis. It is stated by Austin that although tuberculosis of the tonsils in children is not rare, yet most of the cases occur when there are tuberculous lesions to be found elsewhere in the body, especially in the cervical lymph nodes. The occurrence of the tubercle bacillus in the tonsils of children without clinical evidence of tuberculosis, however, is not frequent.

New Stain for Diphtheria Bacillus.—The stain used by Greenthal is made as follows: Kresylecht-violet, 0.07 gm.; methylene blue, 0.1 gm.; glacial acetic acid, 3.00 gm.; water, 100 gm. Dissolve the dye in the acetic acid and water solution, and filter. In a drop of water on a cover glass, make a smear of the growth with a platinum wire. Dry gently over a flame. Place one drop of the stain on the cover glass. Allow it to remain for from one to two minutes, and then shake off the excess of stain. Place a drop of water on the cover and make a hanging mount with a well slide. The preparation can be sealed with the excess of the water. The polar granules are purplish red and the cell body is greenish blue. Most of the other organisms stain very lightly, excepting a few strains of cocci. The hanging drop method makes the organisms appear much larger than they do in the ordinary preparation; a single bacillus is easily seen and differentiated from the surrounding organisms. The stain can also be used with the usual slide method. The polar granules by this method are purplish red and the cell body is light blue, and the contrast is a little better. Greenthal says that this stain is the most successful he has used in searching for diphtheria bacilli in a throat smear preparation.

Antiscorbutic Property of Dried Orange Juice.—Evidence is presented by Givens and McCluggage to the effect that orange juice can be dried so that it retains a significant amount of antiscorbutic vitamin. The most satisfactory process for drying orange juice is the one in which the temperature of drying is not unduly high and the duration of drying is very short. If the orange juice is submitted to a temperature of from 55 to 60 C. for forty hours or more, a part of the antiscorbutic vitamin is destroyed. The dried orange juice investigated by the authors was active after three months storage. It is suggested that the dried orange juice will serve as a convenient antiscorbutic for use in infant feeding, on polar expeditions, in the navy and for soldiers during the war.

- *Quantal Phenomena in Muscle: Methods, with Further Evidence of All-or-none Principle for Skeletal Fiber. F. H. Pratt and J. P. Eisenberger, Buffalo.—p. 1.
*Functional Correlation of Hypophysis and Thyroid. J. A. Larson, San Francisco, Calif.—p. 55.
*Circulation in Shock after Abdominal Injuries. J. Erlanger, R. Gesell and H. S. Gasser, St. Louis.—p. 90.

Quantal Phenomena in Muscle.—A complete account is given by Pratt and Eisenberger of the method for photographically recording the contraction of muscle fibers on excitation with the pore electrode. By the use of the apparatus an experimenter is enabled to watch through a demonstration ocular the movements of the recording mercury globule on the surface of the muscle, while these are being automatically recorded, and at the same time register on the plate, by turning a lever, the actual extent of movement of a secondary coil. Thus the continuity of stimulus variation is shown in a curve coordinate with that which reveals the quantal or discontinuous character of contraction gradients. Full details of principles and construction are shown in drawings, and a

number of graphic records are reproduced, illustrating the different phases and capabilities of the method. On these records further and more complete evidence is based with respect to the "all-or-none" behavior of the skeletal muscle cell in simple contraction, tetanus and staircase and fatigue effects; and the significance of latent periods as obtained by the method is briefly discussed. Emphasis is laid on the opportunity for analysis of mechanical effects which the method furnishes, since the continuous gradients can thereby be differentiated readily from the discontinuous—functions which must always tend to confusion or obscurity in gross muscular action.

Functional Correlation of Hypophysis and Thyroid.—Clinical evidence points to hypertrophy of the hypophysis as a result of thyroid deficiency. The literature clearly establishes the fact that removal of either the hypophysis or the thyroid causes definite changes in the structure of the remaining gland. In the cases of thyroidectomy the consensus of opinion is that the hypophysis undergoes hypertrophy. As to which portion enlarges the most—the anterior lobe is indicated wherever a specific region is mentioned. Larson claims that the administration of the anterior lobe of the hypophysis has a very beneficial action on the maintenance and growth of thyroidectomized rats. Aside from the ameliorating effect on the general condition of the animal, life is definitely prolonged. Larson suggests that the beneficial effect might indicate a direct substitution in which the pituitary autocoid takes the place of the thyroid hormone in a compensatory effort to establish normal metabolism. Or the results obtained might be due to a stimulation effect on the total metabolic processes. A definite decision can only be obtained by extensive study of the various factors involved.

Circulation in Shock After Abdominal Injuries.—In an investigation made by Erlanger, Gesell and Gasser the changes in circulation occurring during the development of shock brought on by exposure and manipulation of the tubes are as follows: The arterial pressure at first may be lowered but little, if any. After some time, it may be after some hours, the pressure begins to fall, and this fall continues more or less steadily, though often slowly, until the animal dies. The changes occurring in the systemic venous pressure have been so small that they cannot be regarded as significant, excepting, perhaps in demonstrating that cardiac failure has little, if anything, to do with the failure of the circulation. The portal venous pressure falls continuously, though slowly, during the first two or three hours. It then ceases to fall or actually rises slightly until the arterial pressure has reached a comparatively low level, when the portal pressure again begins to decline. The peripheral resistance, both somatic and splanchnic, at first practically invariably is increased. At about the time the arterial pressure begins to fall, or starts on its steady decline, and also at about the time the portal pressure starts to rise, the peripheral resistance begins to diminish and by the time the arterial pressure has reached the vicinity of 50 mm. Hg. the peripheral resistance practically invariably is below normal. But up to the time of death the vessels and the vasomotor center preserve some residual tone, though slight reactivity in this respect the findings of Bartlett are completely confirmed. A considerable loss of fluid from the exposed bowel occurs as a result of transudation through the serous surface, and presumably into the tissues also. The capillaries and veins of the intestinal villi are greatly distended and tightly packed with red corpuscles. No positive evidence has been obtained that the efficiency of the heart is impaired during the development of shock. Nevertheless, although the heart is capable of raising the arterial pressure as high as the normal heart can, the authors are inclined to believe that the heart in shock cannot maintain high pressures as long as the normal heart can. The initial changes in the circulation can be explained best on the assumption that the effective blood volume is reduced. The loss of fluid into and through the tissues of the bowel and the sequestration of blood in the intestinal capillaries and venules suggest a mechanism through which a reduction in blood volume might occur.

American Review of Tuberculosis, Baltimore

June, 1919. 3, No. 4

 *Rest and Exercise in Treatment of Pulmonary Tuberculosis. H. M. Kinghorn, Saranac Lake, N. Y.—p. 210.
 Physical Examination in Diagnosis of Early Pulmonary Tuberculosis. L. Nammari.—p. 233.
 Production of Pulmonary Tuberculosis in Guinea Pigs by Means of Finely Divided Droplets of Sputum. J. B. Rogers, Cincinnati.—p. 238.

Lymphatics and Lymph Flow of Lung.—This description of the lymphatics and of the lymph flow of the lung, according to Miller, represents the results of his studies up to the present time. The normal flow of the lymph in both pleura and lung is toward the hilum. Lymphatics form a rich plexus in the walls of the bronchial tree. They possess occasional valves which open toward the hilum. No lymphatics have been seen in the walls of air spaces beyond the ductuli alveolares. The plexus of lymphatics about the pulmonary artery communicates freely with that in the walls of the bronchial tree. Valves have only been seen near the hilum and they open toward the hilum. The pulmonary veins are surrounded by a plexus of lymphatics. The bronchial plexuses of lymphatics are connected by lymphatics which follow those branches of the pulmonary vein which have their origin from the bronchial tree. No valves have been found in the lymphatics situated within the lobule (secondary lobule) of the lung. There is a rich plexus of lymphatics in the interlobular septums and about those branches of the pulmonary vein which are situated in these septums. Such valves as have been found in the lymphatics about the pulmonary vein have been found in the neighborhood of the hilum and they open toward the hilum. In the pleura there is a rich plexus of lymphatics which is provided with numerous valves. In the collecting trunks leading from this plexus all the valves open toward the hilum. The deep lymphatics and the superficial (pleural) lymphatics are connected by a short vessel which follows that branch of the pulmonary vein which takes its origin from the pleura and passes along the interlobular septum. Between the pleura and the point where the first branch of the pulmonary vein coming from the bronchial tree joins that branch of the pulmonary vein situated in the interlobular septum valves are found in the connecting lymphatics which open toward the pleura. These valves also prevent the flow of the lymph from the pleural lymphatics into the deep lymphatics. The short lymphatic which connects the superficial and the deep lymphatics furnishes a by-path for the lymph in case there is obstruction to its free flow toward the hilum near the entrance of the second branch coming from the bronchial tree into that branch of the pulmonary vein situated in an interlobular septum. No lymphatics unconnected with lymph nodes have been seen leaving the lung.

Rest and Exercise in Treatment of Pulmonary Tuberculosis.—The proper employment of rest, in Kinghorn's opinion, is greater than any other single factor in the modern treatment of pulmonary tuberculosis. Almost all physicians advise their lung patients to take plenty of good food and plenty of fresh air, but there are still many physicians who at the same time advise them to take plenty of exercise. This last advice, if given at the beginning of treatment, Kinghorn points out usually does much harm. When the diagnosis of active pulmonary tuberculosis is made, patients are, of course, suffering from active symptoms. At this time the patient should have no exercise, but should have either the reclining rest treatment, or absolute rest in bed, whichever form of rest treatment is indicated. The physician should remember that there is no other disease accompanied by fever in which he advises his patient to exercise. With all other diseases, when there is fever, he at once puts the patient to bed. He knows that if he does not conserve the patient's strength when fever is present, the course of the disease will be bad. No better example of this is seen than in the cases of typhoid patients who walk around with fever for a considerable time before being put to bed. The same rest medical principle of conserving the strength of the patient applies to the patient with pulmonary tuberculosis.

Production of Pulmonary Tuberculosis by Means of Droplets of Sputum.—Twenty healthy guinea-pigs were kept in an atmosphere saturated with a spray consisting of a solution of tuberculosis sputum in sterile water in the proportion of about 1 to 100, for about five minutes. The pigs were then removed, and the mouth and nose thoroughly exposed and swabbed with alcohol. They were then given a complete bath in a 1:5,000 solution of mercuric chlorid. This process was repeated at irregular intervals, usually about seven days, over a period of from six to nine weeks. At the end of this time the pigs were etherized and examined. Rogers found that such an exposure of the nasal passages of guinea-pigs to sprays of finely divided particles of sputum invariably resulted in the development of pulmonary tuberculosis. Other viscera were generally involved, but less uniformly: the mesenteric glands were involved in only 10 per cent. of the cases. On the basis of these findings, Rogers believes, that the probability of bacilli having entered the esophagus and having been swallowed and absorbed from the intestinal mucosa, can practically be discarded. The cervical glands showed tuberculosis changes in 60 per cent. of the cases, and the fact cannot be overlooked that the infection might have entered through the nasal mucous membrane.

 *Simple Splint for Treatment of Fractures of Clavicle. R. L. Hodge.—p. 439.
Pott's Disease and Bone Graft.—Speaking of the use of the autoplatic intraspinal bone graft, Girdlestone says that emphasis must be placed on the preoperative and postoperative treatment; although the operation is in some cases the deciding factor in attaining complete immobilization, and always is most effective in shortening the period of confinement to bed; nevertheless, its success depends on the efficiency of the associated treatment. During this period the operation is added to, but in no way a substitute for, the regular treatment. The graft is only an effective splint when firm bony union is attained. Fifty cases are reported.

Standardization of Joint Records.—Nutter urges that records of joint motion and deformity should be absolutely intelligible, as they are most important in the treatment of the extremities, hence, positions from which measurements are to be taken should be standardized. Diagrams are shown to illustrate the methods advocated by the author.

Splint for Fractures of Clavicle.—Hodge's splint is T shaped. When applied, the cross piece rests as high as possible along and above the superior borders of the scapulae, while the stem extends almost vertically from the body. It is secured in place with bandages. The splint is suitable for both bilateral and unilateral fractures. The fracture is reduced painlessly, and the arms are left free, thus muscular atrophy is avoided. The patient can use the arm on the injured side for any ordinary purposes, such as writing, feeding, etc. Accurate apposition of the fragments of the bone is obtained. Open wounds are easily accessible for treatment without disturbing the apparatus.

Trench Nephritis at British Hospital in France.—A statistical study of the cases admitted to one hospital during the summer of 1917 was undertaken by Fitz in order to determine (1) the relative frequency of this type of nephritis among the medical casualties; (2) the age of nephritis patients as compared with patients with other medical casualties; (3) whether relatively new and untrained troops were more susceptible to nephritis than older and more seasoned troops, and (4) whether evidences of an epidemic form of the disease could be discovered. From the findings which are tabulated, certain deductions may be drawn: Trench nephritis is a form of acute nephritis of unknown origin occurring among troops. It is characterized by the rapid subsidence of well marked renal dropsy, the frequent presence of bronchitis and dyspnea, the suddenness of onset of uremic manifestations, and rarity of occurrence of inflammatory complications, and by an extraordinarily low mortality. It accounts for about 5 per cent. of the medical admissions to a general war hospital and is strikingly more frequent than acute nephritis in a general civilian hospital. It occurs most commonly among relatively older soldiers who have seen service for short periods of time. It occurs to a less extent among the younger and more seasoned troops. It appears to be pandemic and not limited to any single group or groups of soldiers. The dyspnea is not due to acidosis, though slight acidosis is common. Urea retention is found in the majority of cases, and it is most marked in the severest.

The edema is intimately related to chlorid retention and is independent of high blood pressure, albuminuria, or urea retention. Epileptiform convulsions occur in relatively mild cases without abnormal kidney functions and are not associated with urea retention, oliguria or anuria. Cases complicated by convulsion usually have hypertension of varying degree, and all show more or less chlorid retention. It is possible that the convulsions are not "uremic" in nature, but depend on some circulatory disturbance or cerebral edema. Fever at onset in seven cases suggests an infectious origin, an impression confirmed by the tendency to relapse. Two types of relapse are encountered, one febrile in character and associated with symptoms of trench fever, the other having

in addition to fever a definite impairment in renal function. The immediate prognosis of trench nephritis is most accurately obtained by determining the accumulation of urea in the blood and in the urea index. These vary from normal in direct ratio to the patient's condition, tend to approach normal as the albuminuria and hypertension diminish, but are independent of edema and chlorid retention. The ultimate prognosis of the disease is less certain. No relationship is demonstrated between the apparent severity of the disease at onset (as judged by functional tests, physical signs and clinical symptoms) and the length of time necessary for recovery. The indications for treatment depend on the abnormalities in function. As edema is associated with chlorid and water retention, and in the severer cases with urea retention, it is reasonable to restrict fluid intake and to give diets low in chlorid and nitrogen. When the blood urea concentration has become normal and the edema has disappeared, cases should be managed as cases of chronic nephritis and observed carefully until they are well.

Malaria Control: Disinfecting all Patients Treated.—Bass emphasizes the point that if 20 per cent. of the cases of malaria were disinfecting during a given year, it would reduce the cases of relapse that would occur during the following year 20 per cent., which would represent 10 per cent. of the total amount of malaria that would otherwise be expected to occur. Not only would it do that, but it would also reduce the chances of transmission and occurrence of new cases to the same extent, or approximately 10 per cent. of the total number of cases that would otherwise occur. It would appear, therefore, that if all doctors in a given locality disinfect all of their patients by efficient treatment, there would be a reduction of 20 per cent. in the total amount of malaria each year. It would take about four years to reduce the prevalence 50 per cent. if the physicians disinfect all of their malaria patients. The chief causes of failure at the present time are believed to be (a) spectacular methods of treatment, (1) not

giving patients convincing advice as to the nature of the disease and necessity for proper treatment, and (c) not advising efficient treatment.

Tuberculosis of Cervix Uteri.—In Moore's case the disease involved the tubes, fundus and cervix of the uterus. The process was oldest in the tubes where there was caseation in addition to giant cell formation and an accumulation of many endocervical cells. In the uterus and cervix the process was limited to the mucosa and consisted of the formation of fairly numerous miliary tubercles. The underlying muscle tissue was not involved in the slightest degree.

Choice of Method in Operations on Pituitary Body.—The essential difference between the two methods described by Frazier is that in the original, the approach to the sella was extradural, whereas as now practiced, the approach is intradural. This modification introduces a T-shaped incision in the dura with its horizontal limb on a level with the supra-orbital ridge and the vertical limb extending down toward the sella turcica. By this slight change in technic, the frontal lobe is elevated with greater facility and the view of the sella region is very much more satisfactory. Furthermore, the intradural route avoids the necessity of removing the roof of the orbit, a rather tedious step in the original technic.

Study of Bladder Function.—A study of the effects of non-catheterization of the paralyzed bladder was made by Curtiss in the case of twenty-two male rabbits. Extreme distention occurred thirteen times, with spontaneous rupture of the bladder in one instance. Nine showed extensive vesical erosions or ulceration. Back pressure with ureteral and kidney pelvis dilatation was usually present; in six cases this caused wide patches of almost complete destruction of kidney tissue. Bacterial invasion of the urinary tract was demonstrable in ten of the twenty-two animals operated on. These experiments on rabbits indicate that the unrelieved paralyzed bladder offers a twofold menace to health: first, through frequent infection of the urinary tract due to contamination of static urine; second, through back pressure which distends the ureters, seriously interferes with kidney function and damages the kidney tissue. It would appear advisable, therefore, to maintain the paralyzed bladder in a state of freedom from residual urine, thus minimizing the damage of kidney involvement. Observation in surgical cases in military service has convinced Curtiss that post-operative retention in men is quite infrequent as compared with women. It is further probable that the latter develop a

higher percentage of infections. Except in instances of bladder paralysis or obstructed outflow, the problem of vesical retention is, therefore, chiefly concerned with the female sex. Curtiss emphasizes that irregularly performed catheterization for retention of urine is unsatisfactory. Carefully managed catheterization of the bladder which fails to empty spontaneously yields excellent results; but the catheter should be passed regularly and often enough to prevent vesical distention, and its use must be persisted in until daily tests show that residual urine is no longer being retained in the bladder.

Excision of Vesical Diverticulum.—Rathbun urges the removal of the whole diverticulum, not merely its mucous membrane. He does a two-stage operation. In the first stage he stretches the orifice of the diverticulum to provide better drainage and in the second stage, the diverticulum is excised.

Traumatic Rupture of Normal Spleen.—Four cases are cited by Willis. The patients were all males. A blow on the left side of the body in the splenic region caused the rupture, but there was no external evidence of injury of the body; rigidity and tenderness of the abdomen were present. All of the patients had shock following the splenectomy. In each case all the spleens were practically normal in size with short pedicles and without any history of previous disease of the organ. Three of the four patients had agonizing pain in the left shoulder, which was promptly relieved by splenectomy. Three patients were operated on twenty-four hours after the injury. In two of the cases a marked increased leukocytosis persisted after the operation over a period of from two to four weeks. These three patients had a satisfactory convalescence. One patient died eight days after operation. In this case there was a continuous fall in hemoglobin and a decreasing leukocyte count. In the first two cases operation was followed by direct transfusion, with apparently good results. The fourth patient, a child, could not be operated on because of coexistent concussion of the brain.

Malignant Leiomyomas.—Malignant leiomyomas, according to Proper and Simpson, are not infrequent and if a more careful examination of all "fibroids" were made they believe that the statistics reported in the literature would be greatly increased. They report twenty-two cases in which the diagnosis was based on careful microscopic examination.

Terminology in Cancer of Breast.—This paper is based on a study of 2,100 specimens of breasts received for various reasons. The inaccuracy of clinical diagnosis and the necessity and value of microscopic diagnosis are emphasized. MacCarty and Connor urge the adoption of terms which are not only descriptive and correct but which can be used with facility by both the pathologist and the clinician, in other words, a common pathologic language. The basis of such a language is described and terms are proposed.

Irritation of Dura as Cause of Headache.—Rogers is convinced that chronic irritation of the dura is a common cause of headaches. The most frequent irritation in his experience has been the deposit of lime salts in organized extradural or, strictly speaking, subperiosteal blood clots. After the acute hemorrhagic condition subsides the patient may apparently be well for weeks, months, or even years before any localized symptoms manifest themselves. The symptoms are pathognomonic and can be recognized easily. There is usually a history of a previous injury which may have been considered trivial by the patient at the time, and has long been forgotten until headaches appear. They are always localized in a definite area on the skull. The headaches may be constant but more frequently they are paroxysmal. They are exaggerated by bodily and mental fatigue, and are more frequent at night. They are agonizing, of a gnawing, tearing character, and often associated with dizziness and vomiting. The pulse, temperature and respirations may be normal and the blood count negative. During the attacks the cerebration is slow. The attacks may be epileptoid in character, and the patient may be mentally irresponsible for his acts and deeds. It is not uncommon for these people to become heavy drinkers, using profane and most vile language during the seizures. They become adept liars and may resort to petty

thievery. As the attacks become more and more frequent and severe, it is not at all unusual to find these persons declared insane and sent to sanatoriums for treatment. The insanity disappears after the removal of the irritant and the patient becomes normal mentally in his acts and habits. Cases are cited.

Tendon Transposition.—The results of experimental work done in connection with the surgery of tendon transplantation and tendon transposition are detailed by Bernstein. He points out that the function of a surgically transposed tendon separated from its normal surrounding structures is interfered with (1) by disturbances of its nutrition; (2) by mechanical obstructions to its motion, i. e., adhesions; (3) by a change in the nature of its regenerated tissues. The true physiologic method of transferring the function of a tendon to a new insertion is to transpose it with all its necessary peritendinous structures and with the minimum amount of surgical traumatism. The proliferative and infiltrative changes observed by Bernstein when an exposed tendon is transposed directly to a new insertion leads him to believe that these changes are permanent, and although not marked enough to destroy the vitality, they are such as might interfere with the functioning of the tendon. Transposing a tendon to a new insertion stripped of all its surrounding tissues therefore appears to be unphysiologic, because (1) it deprives a tendon of its nourishment and (2) exposes a susceptible tissue to irritation and thence to the formation of adhesions. In a second series of experiments the tendon was transposed through the sheath of another tendon. In this method the tendon sheath is opened and the tendon separated from its surroundings (mesotendon, etc.). Sutures are inserted in the distal end. This forms a more or less thick rough stump. The tendon is now forced through the sheath of the paralyzed tendon. The final results obtained are an improvement on the older methods of transposition. The results are shown by the histologic findings. There are no inflammatory processes between the tendon and the sheath, and no opportunity for the occurrence of adhesions. The epitendon and endotendon remain unimpaired. Such reaction as is observed has very little effect on the functional action of the transposed tendon. This method of transposition also avoids the possibility of fibrosis of the tendon, a condition which was observed in other methods. This fibrosis is a nutritional disturbance of the tendon and is brought about by separating the tendon from its blood supply, the mesotendon and its surrounding connective tissue structures. Bernstein's method of transposing a tendon, preserving its normal anatomic surroundings and obtaining results by which the tendon in its new position fulfils its normal functions is claimed to be the true method of transposing tendons. Bernstein advocates a special method of inserting the sutures, one which avoids fraying or tearing of the end of the tendon.

Intrinsic Trifid or Double Hour Glass Stomach.—Burke reports a case of true intrinsic trilobular stomach due to cicatricial contraction of chronic gastric ulcers which he believes to be the only genuine intrinsic double hour glass stomach on record.

Surgery of External Carotid Artery.—Nicolson claims that in the average hands ligation is a simpler procedure than Crie's compression; that it controls the same area of arterial distribution, and carries less risk of cutting off circulation from the brain. He describes his method of ligation.

Prostatectomy.—In Ochsner's method with the patient in the lithotomy position, a grooved sound is introduced into the urethra down to the perineum. An incision is then made corresponding to the lateral incision formerly practiced in the operation of perineal lithotomy, extending from a point half way down the scrotum and anus, to a point half way between the left tuber ischii and the anus, and extending down into the membranous urethra which is opened at this point sufficiently to admit the point of an old fashioned lithotomy knife. The sound, together with the lithotomy knife, are passed into the bladder, care being taken to carry the sound along the pubic bone to prevent the knife from cutting into the rectum, thus splitting the membranous and prostatic urethra posteriorly. The knife is then withdrawn

and the operator's finger is carried through the incision along the sound into the bladder. The finger is now precisely in the same position as it would be if a suprapubic opening had been made, and in this fact, Ochsner says, lies the important advantage of this over the other methods of operation, because beginning from above and entering the capsule of the prostate through the urethra, one is in a position to enucleate the prostate precisely as though the bladder were entered from above through the usual suprapubic incision and the prostate were to be enucleated according to the Freyer method. This step of the operation should be carried out with the utmost care in order not to disturb the bladder or urethra unduly. The index finger of the left hand is then introduced into the neck of the bladder, and the capsule of the prostate is caught by means of fine toothed forceps, one being applied to the right and one to the left, and a drainage tube consisting of an inner tube 1 centimeter in diameter and covered in its middle portion by a second rubber drainage tube just large enough to slip over the first one, is introduced into the bladder, the inner tube extending into the bladder, and the outer tube into the capsule. The double tube prevents collapse, and offers a sufficient amount of resistance to make the tamponing effective for controlling the hemorrhage. The rubber tube is held in place by means of silkworm-gut sutures which pass through the edge of the wound and the outer rubber tube. Two days after the operation the tube and packing are removed.

Use of Automobile Inner Tubes to Provide Lung Exercise.—Smith instructs his empyema patients to blow up an old inner tube from which the valve has been removed. This exercise should be done several times daily after the acute symptoms have passed.

Physical State of Blood Serum in Relation to Its Agglutinin and Antibody Content.—By submitting blood serum and other body fluids to a mechanical process, which includes friction combined with pressure, Bond claims, physical changes can be brought about in these fluids which throw some light on the condition in which hemagglutinins, bacterial agglutinins, complement, complement deviating substances and antibodies exist in the blood serum. They suggest that the blood serum and the body fluids, the secretions and excretions, form a graded series with the blood serum at one end, and the excretions, such as the urine, at the other. The hemagglutinins seem to be present for the most part in a free state in the blood serum, and in a more or less combined form in the transudates and exudates, while in excretions, like the urine, the hemagglutinins when liberated and recovered in the free state are found to have lost their specific character. This is shown by testing the agglutinating capacity of the fractional series of liquids and sediments to the same varieties of washed cells. Not only do the hemagglutinins show marked differences of composition in the different liquids and sediments, but they also vary according to the extent to which the fluid has been submitted to the mechanical fractional process. This is also true of the bacterial agglutinin contained in blood serum, and it has been found possible by these means to increase considerably the agglutinating titre of a blood serum to a given organism while retaining at the same time the specificity of the reaction. This suggests that it may be possible to raise the agglutinating capacity of a serum by a mechanical process in vitro for therapeutic purposes. These observations also show that the complement

deviating factor in positive syphilitic serums passes over along with the hemagglutinins and bacterial agglutinins into the liquor, and is not thrown down with the sediment.

Hypnosis in Treatment of Mutism.—One hundred and twenty-one cases of mutism were treated hypnotically by Brown. Every one of the patients spoke when made to live again through their terrifying experiences. Some of them stammered, but these were a small minority. Brown did not need to give a specific suggestion that they would be able to speak. Cardiovascular and secretory changes (tachycardia, hyperhidrosis, etc.), dependent on disturbances of the sympathetic nervous system, showed alteration under the same method of treatment. Curiously enough, paralysis of the voluntary muscles (apart from those concerned with the voice) diminished less readily than other symptoms. On the other hand, voluntary paralysis cleared up, sometimes quickly, sometimes slowly, under the influence of suggestions and persuasion, without the need of hypnosis.

Transvenous Aneurysmorrhaphy.—The method employed by Pearson to introduce the suture to close the arteriovenous communication is as follows: The needle is first passed through a small portion of the fibrous tissue which binds the vessels together at one end of the communication, on the external aspect (that is, entirely outside the vessels and between the two), and does not penetrate the intima of either vessel; it thus resembles the commencement of the outer row of sutures in a gastrojejunostomy. This stitch is immediately tied and the needle is then passed obliquely from without inward, emerging on the inner surface of the vein close to the extremity of the stoma. The extreme edges of this are then brought together by fine continuous sutures through intima and media until the opposite end is reached, when the needle is again passed out from the lumen of the vein obliquely through its wall and the overlying tissue which binds it to the artery, so as to emerge between the two, when it is secured in a similar manner to the other end. There is no knot projecting in the lumen of either vessel, and if the stitches are placed accurately and drawn taut throughout they do not present in the lumen of either vessel any more than in the case of ordinary through and through stitches which produce eversion of the edges in vascular suture. The closure of the incision in the vein is effected by the method advocated by Carrel.

Osteoplastic Closure of Cavities in Bone.—Marshall is convinced that bipp filling of bone cavities is in every case a successful method of treatment provided always that the preparation is thorough. There are types of cases: (A) The larger group—where a sufficient thickness of soft tissues is present to cover the opening—here simple filling is adequate. (B) Where no soft tissues can be placed over the opening which lies flush with the skin: These cases can be treated successfully by covering with a skin and bone flap and filling the cavity with bipp. The advantages are: Less extensive disturbance of tissues than in any other operative procedure for closure of the cavity—no small consideration in war scars. Anatomic restoration of the bone is achieved; strengthening and not weakening results; fresh osteogenic surfaces are exposed; a good cosmetic result is obtained. The objections are: A foreign body is left in the tissues; but it (a) combats infection, (b) stimulates osteogenesis, and (c) it is removed naturally when these goals have been attained. Sepsis is neutralized by adequate preparation, careful technique and bipp. A plastic bone operation is not to be approached lightly in the presence of the slightest sepsis; but (a) the bone used is more vascular than normal;

(b) the exceedingly vascular bone at muscular insertions can be used; bipp smearing prevents infection.

Chronic Bony Fistulas.—Stoney uses bipp in these cases. The operation must be planned after the results of roentgen-ray examination are known. If possible the fistulous track should be excised right down to the bone, and the more of the fibrous scar tissue used the better. When the bone is reached, the periosteum should be raised for some distance all round the opening. The whole infected area of the bone should be explored thoroughly and laid open, all sequestrums and foreign bodies should be taken away, all overhanging walls removed by forceps or chisel, until the walls of the cavity in the bone slope gradually to the deepest point. If possible the bony walls should be gouged away till healthy bone is reached, as is shown by free oozing from the cut surface. The whole wound is now dried and swabbed with ether or methylated spirit and packed for a couple of minutes with gauze wrung out of one or other of these liquids. Modified bipp (iodoform, 2; bismuth, 1, and petrolatum, 12) is then rubbed into the walls of the bony cavity, which finally is filled with it. If the cavity is small and regular, and it has been possible to remove its original walls fairly completely, and if there is a good depth of healthy tissue between it and the skin, the wound may be closed in layers, using one or two layers or even more of catgut for the periosteum and muscles, and silk impregnated with bipp for the skin and superficial fascia with a few sutures of fine silk-worm gut to obtain good coaptation of the skin edges. Gauze smeared with bipp is placed over the wound and a thick layer of wool and a firm bandage is applied. If all goes well, the dressing need not be changed till the stitches are removed about the tenth day, when the wound will be found fairly healed. Eighty-eight per cent. of cures are claimed.

Method of Securing Rapid Healing of Bone Sinuses.—Immediate success was secured by the Henrys chiefly by instillations every two hours of Daufresne's standardized solution of hypochlorite, after the method of Carrel. Another postoperative treatment which occasionally gave good results was the daily injection of iodoform and bismuth subnitrate suspended in liquid petrolatum used alone or alternately with Carrel instillations.

Operative Treatment of Tuberculosis of Larynx.—Rüedi claims that tuberculosis of the larynx is curable. Spontaneous improvement as well as cure can be observed repeatedly in Davos under the influence of general treatment, but it is denied that improvement in the pulmonary condition has a favorable effect on the laryngeal lesion. In several cases the fresh air cure, as also the usual local conservative treatment, in particular heliotherapy, were in sufficient or ineffectual, notwithstanding improvement in the pulmonary condition. A considerable proportion of these patients could be cured by operation. According to Rüedi operative treatment of tuberculosis of the larynx should be undertaken only in cases in which there is no fever and the pulmonary condition is stationary, exception being made for cases in which urgent symptoms demand interference. The best method is electrocauterization (Mermod-Seibenmann's method) with its broad and deeply destructive radical effect. Only in cases of tuberculosis of the epiglottis did curatting prove itself better than resection or amputation. Operative treatment resulted in cure in a little more than a third of the number of cases followed and checked. The best results (62 per cent. of cures) were obtained in the electrocauterization of the cords. Operative treatment exercised in several cases a very favorable influence on the lungs and on the general condition. The contention that a stay at a high altitude is contraindicated for tuberculosis of the larynx Rüedi claims is wrong. Even in cases of pulmonary tuberculosis complicated by laryngeal tuberculosis a stay in the high mountains is indicated in accordance with modern experience of both. When the altitude has a favorable influence on the pulmonary, without being able to ameliorate the laryngeal lesions, one must employ local treatment by electrocauterization according to Mermod-Seibenmann's method which can bring about a particularly rapid cure under the favorable influence which the climate of the high mountains exerts on the vitality of the organism.

Syphilis: When Is the Patient Cured.—Dinnick says that if after an intensive course of arsenical medication and the continuous exhibition of mercury for two years, a patient can show two years' freedom from physical signs of disease, has a persistently negative blood serum, a spinal fluid which shows no variation from normal in either pressure, globulin content, or cellular count, and which gives a negative Wassermann in amounts of 2 c.c.; and if after a period of freedom from treatment these conditions are still present and persist in spite of provocative treatment, it is justifiable, in our present state of knowledge, to presume that the patient is cured. Finally, should this patient subsequently develop a fresh chancre at a site differing from the first, this would be a reinfection. For syphilis does not confer immunity, and the real interpretation of all alleged immunity is that the so-called immune person is an active syphilitic.

Cerebrospinal Fever.—One hundred cases of epidemic meningitis chiefly due to the meningococcus were analyzed by Carter and Boyes. The average age of these patients was 23.5 years. Certain camps, without a necessarily larger body of troops present, furnished a larger number of them, and more fatal cases, spread over the whole period. No satisfactory reason for this is forthcoming. No seasonal or meteorologic condition can be shown to have influenced the incidence or death rate, except that the larger number of cases occurred in the three winter months, December, January and February. No single symptom can be considered pathognomonic of the disease, and even a combination of the principal symptoms may not be positive. A positive bacteriologic finding alone is conclusive. No treatment appears to be so effectual as early continued lumbar puncture and injection of serum. Wherever possible a serum of the particular type affecting the patient is preferred. The most frequent and the most fatal type was Type 2.

Diaphragmatic Hernia.—Of seven cases analyzed by Warren three were the result of gunshot wounds of the chest and abdomen, a fourth had suffered from fractured ribs on both sides in a buffer accident. Of the other three, two were young people, with no history of injury, and probably due to congenital defects; the last case was a female, 68 years of age, with a long history of failing and vomiting, with no history of injury, and so it may also have been of congenital origin. In four cases the opening was about 2 inches in front of the esophageal opening, in the other two the position is not mentioned. In three cases the contents of the hernia were stomach; in two, large gut; in two, small gut. In five cases there were acute obstruction and strangulation, and in one case subacute obstruction of a recurrent type, in one case no obstruction but an associated pyloric ulcer, laparotomy for which led to the discovery of the more rare condition. Diagnosis was only made during a laparotomy done for treatment of the obstruction, or in one case to treat a pyloric ulcer.

Bone-Grafting Operations in Ununited Fractures of Mandible.—According to Munby and Shefford bone-grafting

operations give the best results when there are teeth in both fragments, which can then be controlled by a splint. In nine cases of such a nature, all except one were united at the end of ten months, giving 69 per cent. of complete successes. In those cases where there is an absence of teeth in the posterior fragment the operation is only indicated when the pseudoarthrosis is very lax, and marked improvement can be obtained, even if union of the graft is imperfect. Where there is already firm fibrous union causing little or no disability, the operation is not indicated. There were eight such cases in this series; in two cases bony union was obtained, three patients were considerably improved, and two remained in statu quo. Better results are obtained by the use of pedicled grafts than by free grafts. Certain cases where there is a large gap between the fragments are not suitable for a pedicle graft, especially when both ends of the fragments are pointed. In such instances a free graft is preferable. In free grafts the best results are obtained when the graft can be wedged into position and the periosteum stitched with fine catgut. Absence of wound infection is an essential in order to secure satisfactory results.

Case of Myomectomy During Pregnancy.—Because of intense pain in the right iliac region, Farmer operated on a woman, three months pregnant, for fibroid. The mass was shelled out. A fairly deep crater was left, but the uterine cavity was not exposed. The muscular walls of the crater were closed up by catgut mattress sutures and then the peritoneal cuff was inverted and closed by a continuous Lembert suture of cotton thread. The abdominal wall was closed in the usual way. The growth removed weighed 425 gm. The patient made a perfect recovery and was delivered of a healthy boy.

Auricular Flutter and Other Cardiac Cases.—According to Silberberg, auricular flutter is not uncommon in old people. The persistent, rapid pulse rate, with periods of irregularity and occasionally doubling of the speed from exertion or excitement, should suggest a possible flutter. The electrocardiogram is the surest means of diagnosis. Treatment by digitalis is satisfactory. The electrocardiogram reveals characteristic curves in the hypertrophies. It gives positive evidence of dextrocardia, because the curve is completely reversed in Lead I. In lesions of the branches of the conduction system it gives clear evidence of myocardial degeneration, an important sign with serious outlook. Cases of auricular fibrillation are quoted to show various possibilities and the great value of digitalis therapy.

Surgery During the War. P. Dorel.—p. 162.

Plastic Motor Surgery After Amputation.—Pellegrini has now a record of twenty-seven cases in which he adapted the stump after amputation to ensure more or less volitional control of the prosthesis. The outcome is regarded as a success in all but three cases. He discusses technical points, much the same as in his previous articles abstracted in THE JOURNAL, 71, 1173 and 2029, 1918, and brings the history of kinetic plastics down to date.

Meningococcus Septicemia.—Colard classifies seven different forms of meningococcus septicemia, and then emphasizes the inefficacy of ordinary methods of treating it. The tendency to relapses is pronounced. In one of his cases there were five relapses, the cerebrospinal fluid becoming clear and sterile in the intervals. Septicemia was evident in 25 per cent. of his sixteen cases of epidemic meningitis, and the importance of giving the antiserum by the vein is emphasized by his experience, as also the necessity for supplementing the serotherapy with an autogenous vaccine. His experience in Noll's service has confirmed the advantages of giving the autogenous vaccine by the vein, beginning with small doses. He injected this every fourth day 1 c.c. of an auto-vaccine obtained from a culture killed by heat at 55 C. for half an hour, with addition of 0.5 per cent. of phenol. The initial dose was 50,000 microbes, then 100,000, 200,000 and so on per c.c., progressively increasing if there were no phenomena of a general reaction. This intravenous bacteriotherapy seems to be the necessary complement to serotherapy when the latter alone does not suffice. One of his patients developed a phase of anaphylactic symptoms eight days after an injection of the antiserum but it yielded to epinephrin.

Ignored Syphilis.—Dujardin relates that pupil anomalies first gave the clue in 95 of his 216 cases of ignored syphilis. Anomalies in the reflexes gave the clue in 35; usually the Achilles reflex was the one at fault first, but unequal abdominal reflexes were also instructive. Leukoplakia of the tongue is almost a certain sign of syphilis, but in 28 of 80 cases of leukoplakia elsewhere in mouth or lips, nothing suggesting syphilis could be detected. Dizziness or nervous deafness gave the clue in 5 cases, and laryngeal lesions in 3. Vitiligo and alopecia were found in 4 and 6 cases, mostly with inherited syphilis. Zona of the lower half of the body was generally found associated with a chronic syphilitic meningitis.

War Radiotherapy. H. Bordier.—p. 688.

Disorders between Subjective and Organic Symptoms with Stomach Disease. L. From.—p. 690.

Neo-Arsphenamin in Filarial Chyluria.—Deschamps reports a second case of this kind, the injections of neo-arsphenamin resulting in the disappearance of the filaria from the urine. The urine coagulated in the bladder to such a degree that it clogged the urethra. This was overcome by giving sodium citrate, after which the urine seemed to become more fluid.

Arsphenamin Apparently Wards Off Syphilis.—Dancier tells how a Belgian, chief of the French Hospital at Manchester, inoculated himself, March 21, 1918, in the presence of twenty other soldiers, with a little serous fluid from a syphilitic chancre. In less than an hour afterward he was given an intravenous injection of 0.6 gm. of arsphenamin. No local or general symptoms of any kind followed, and the Wassermann test applied every month since has been constantly negative.

Organized Prophylaxis at Paris.—Sieur describes the work of the preventorium against tuberculosis and against venereal diseases in the Paris district during the war, and also the crèches and various other welfare institutions for factory workers and children, all organized by the military medical department.

Retention of Chlorids and Urea in Nephritis in Children.—Nobécourt explains that the different types of nephritis observed in adults are encountered also in children, in both the acute and chronic form. Study of the elimination through the kidneys enables the different phases of the kidney disease to be followed. It shows the different retention at different periods, and explains the brief course in some acute cases and the latent or intermittent character in certain cases. Persisting retention of chlorids or urea, even if slight, is a warning sign. Modification of the diet usually puts an end to the retention; if the edema does not subside, small doses of digitalis or theobromin kept up for five to ten days usually stimulate diuresis. His dose of theobromin is below 0.6 gm. for large children. It loses its efficacy in about a week; if kept up too long, it is liable to bring on or increase albuminuria. In certain acute or chronic cases of nephritis with chloridemia, the edema is irreducible. In 12 cases of acute nephritis there was strong azotemia (1 to 6 gm.) in 5, plus chloridemia in 3; moderate azotemia plus chloridemia in 3, and in the 4 others there was chloridemia but no azotemia. In 10 chronic cases of nephritis the urea was less than 0.5 gm. per liter in 7, while it was from 0.5 gm. to 1 gm. per liter in the others.

Fatal Poisoning from Barium Salt.—Bensaude and Antoine some time ago extolled the great advantage of barium sulphate as an opaque substance, harmless to man while extremely useful for roentgen work. Bensaude published in 1917 his endorsement of the barium sulphate contrast meal. He now emphasizes that the fatalities which have followed its use are due to the druggist's having blundered and dispensed the carbonate or sulphide in the place of the ordered sulphate. Two fatal cases are described, the patients a woman of 27 and man of 37. The robust woman died ten minutes after ingestion of the suspension of a tablet of 40 gm. of barium polysulphid. The man took 80 or 100 gm. of barium carbonate and vomited part of it the third hour. He was given sodium sulphate and magnesium sulphate which combined with part of the barium salt to form an insoluble compound so that death did not occur until the thirty-fifth hour. A number of other mishaps of the kind are on record, for all of which the pharmacists' blunders were responsible, dispensing the chlorid, sulphid or carbonate of barium in place of the insoluble and stable, harmless, chemically pure barium sulphate.

Persisting Subfebrile State with Unstable Heart.—Summarized in the Paris Letter, p. 1929.

The Intradermal Tuberculin Reaction.—Pruvost reports the repeated application of the intradermal test to eighty-three persons suspected of tuberculosis. The most instructive response was obtained with 0.1 c.c. of a 100,000 or 200,000 dilution of the tuberculin.

Medical Treatment of Purulent Pleurisy.—Weil and Loiseleur expatiate on the advantages of repeated punctures, injection of air, and possibly injection of methylene blue in treatment of purulent pleurisy. Eleven of the twelve patients treated in this way recovered, but seven of them required operative measures finally. The delay did not seem to have done any harm, while it permitted those capable of recovering under medical treatment alone to get a chance to do this. This occurred in two cases of total purulent pleurisy and in four with localized processes. There is no need for operative intervention if the pus forms again very slowly and the amount is found less at each puncture, and the intervals between punctures can be lengthened while the general condition improves to correspond. If the weight increases, this

is a further sign of general improvement. Their medical patients gained from 10 to 25 pounds while the suppuration was gradually subsiding.

Surgical Treatment of Paratuberculous Pleurisy. H. C. Schultz de Brum. (New York).—p. 202.

Thymol for Expulsion of Tapeworm. X. Arnozan.—p. 205.

Lambliosis.—Carles emphasizes the chronic and tenacious character of lambliæ enteritis. Some of his patients had been treated long for enteroneuroses, insufficiency of the liver, or even intestinal tuberculosis, and the lambliosis had been overlooked. One young man had been affected with this chronic enteritis from early childhood, and it had impeded both physical and mental development. The lambliæ may be found in the mucus from the rectum, but usually it can be discovered only after purging and centrifuging the sieved and homogenized stools. Sulphur has proved most effectual in his experience, from 2 to 6 gm. a day, in three doses, kept up for ten days. By repeating this course every month for a time, recurrence is warded off. Other parasites require their special treatment. Every recurring enteritis should suggest lambliosis.

Treatment of Bone, Gland and Skin Tuberculosis.—Chénut describes the fine results he has obtained with sun baths and sea baths in what used to be called surgical tuberculosis.

Journal de Radiologie et d'Electrologie, Paris

May, 1919, 3, No. 5

*Accessory Focal Spots in Roentgen Tubes. A. Lumière.—p. 193.

*Comparative Value of Roentgen Ray Tubes. H. Guilleminot.—p. 205.

*The Resistance of the Human Body to the Electric Current. A. Strohl.—p. 207.

*Magnet for Extraction of Scraps in the Brain. Costantini and Gosse-
lin.—p. 224.

Accessory Focal Spots for Rays Discharged by Tubes Used in Radiology.—Lumière cites those who have been making a study of the accessory sources of the roentgen rays, and then describes similar research undertaken with the tubes as usually employed in radiology and also with all the sources of the principal or parasite rays discharged by the apparatus producing the roentgen rays. Some of the radiograms were taken with the tube turned completely around, the exposures made through the thin plate of the anticathode, directly opposite to the usual direction of the rays. The roentgenogram was as perfect (with the Muller tube) as when the routine conditions had been exceptionally favorable.

Comparative Tests of Roentgen Tubes.—Guilleminot describes how to compare the sharpness of the images, the total output of rays per current, and the endurance of the tubes. The fluorometer is the main reliance in the tests.

Electrodiagnosis.—Strohl remarks that most of the methods of electrodiagnosis presuppose an invariable resistance on the part of the tissues to the electric current. But this resistance is not invariable. It depends on a number of variable factors, as he explains in detail, with suggestions how to eliminate various causes of error.

Cure of Radiodermatitis with Carbon Dioxid Snow.—Aubourg reports the case of a radiologist who had always used most scrupulously the current means of protection in his thirteen years of roentgen work, even to a doubly protected glove for the left hand. But in 1912 chronic lesions developed on his hands. He kept at his work during the war, often making long exposures in restricted quarters. In two years he had thus aided in extraction of 4,000 foreign bodies. The chronic dermatitis was then treated once a month with carbon dioxid snow, applied for forty seconds at each sitting to one, two or three of the foci. The focus was then treated with bismuth held in place with a gauze bandage. This dressing was left undisturbed for ten or fifteen days. The eschar dropped off the fifteenth to the seventeenth day, and

by the end of two months there was not even a trace of scar. During the entire course of treatment the hands were kept well greased at night with a soothing salve. In thirteen months twenty-three lesions were thus treated and twenty-one subsided smoothly; one started to suppurate but this was at once aborted with magnesium chloride, according to P. Delbet's technique. One other lesion returned at the end of three months as a wart on the spot that had been treated and had disappeared. This recurring lesion rapidly progressed but was treated and soon healed like the others. There was also a warty growth on the left forearm which looked so suspicious that excision was recommended for this, but it disappeared spontaneously while the other lesions were being treated. One would have to look close now to suspect that the hands were the hands of a radiologist. The carbon dioxid treatment did not interfere with his continuing his work; its efficacy is apparently established by the year and a half that has elapsed since. The case teaches further that the most painstaking care to avoid danger is not always effectual, as we cannot rely implicitly on the protecting devices at our disposal.

Lyon Médical

May, 1919, 123, No. 5

*Dysentery and Edema. Martin and Delbard.—p. 225. Cont'n.

*Eosinophilia. E. Deglos.—p. 231.

*Case of Fatal Gonococcus Septicæmia. Leclercq.—p. 238.

*Pathogenesis of Fever. Widmann.—p. 241.

Eosinophilia.—Deglos comments on the local eosinophil reaction often seen in effusions of traumatic origin and in exudates, subcutaneous or conjunctival, as also the general eosinophil reaction in the blood in various conditions of infections or of purely toxic origin from microbial or parasitic toxins. The reaction seems to be more to the toxins than to the microbes or parasites themselves. The eosinophilia persists long into convalescence and may aid in the retrospective diagnosis in connection with the tracheo-bronchial gland changes. One patient with severe enteritis and intense anemia had pronounced eosinophilia for which no cause could be discovered until it was casually learned that during his visits home, twice a week, he was subjected to severe carbon monoxid poisoning from a charcoal stove. The cases of eosinophilia hitherto classed as nonsymptomatic are being cleared up by such discoveries, and especially by the research of Weinberg and Seagun reported recently in the *Annales de l'Institut Pasteur*.

Pathogenesis of Fever.—Widmann is now convinced, for reasons which he enumerates, that fever in most cases is a defensive reaction by means of production of sugar to an extent far above normal, plus an intense utilization of the sugar thus elaborated. In every fever the first thing to be done is to ascertain the condition of the liver and to improve its functioning by every means in our power. This should include (1) copious drinking of sweetened beverages while (2) alcoholic drinks should be taken with extreme caution. Another indication (3) that Widmann emphasizes is to make the patient vomit if not too much enticed by the malady. And also (4) to give quinin, 10 grains at a time, every three hours until the stools are diarrheic in case of cholera. And finally (5) not to allow him to walk about. The bases for these directions are (1) because sugar given by the mouth reaches the liver, by the portal system, and helps the liver in the production of glycogen; (2) because alcohol, possibly useful at first as a general stimulant and hence a stimulant of the liver, soon displays a paralyzing action on the central nervous system, and this has a grave depressing influence; (3) because emetics have a stimulating action on the liver; (4) because quinin stimulates secretion of bile and probably also the secretion of glycogen, as all of the liver functions seem to be closely connected, and finally (5) because walking about uses up glycogen and throws an extra task of glycogen production on the liver. Typhoid fever is peculiarly dangerous in a diabetic as the liver is already below par. The sugar may disappear from the urine as the fever rises. But the patient soon dies. The sugar from the food is transformed into glycogen owing to the intense stimulation of the liver, but this stimulation is more than the diabetic can bear, and he succumbs. The article is to be continued.

Paris Médical

- Measures for Aiding Tuberculous Ex-Soldiers. L. Bernard.—p. 405.
 Psychic Symptoms with Recent Brain Wounds. B. J. Logre and H. Bouttier.—p. 408.
 Neoarsphenamin in War Surgery. A. Bréchet.—p. 414.
 Physiopathology of the Bladder Sphincter. R. Uteau.—p. 416.

Tuberculous Ex-Soldiers.—Bernard reviews the history of what has been done in the past to aid the tuberculous discharged from the army. He refers especially to the work of the Comité départemental de la Seine district founded in 1910 which included children also in its welfare work.

Psychic Reactions to Brain Trauma.—Logre and Bouttier remark that the varied war traumatism affecting the brains of strong young men induced a special reaction, evidencing the autonomy of traumatic mental pathology and the marked difference between this and all other modes of diffuse psychopathic reaction such as emotions, mania, melancholia, toxic-infectious confusional states, etc. The dissociations induced have a decided diagnostic value and form a guide to treatment, especially in the line of surgical neuropsychiatry. This special pathology determines the remote prognosis by the modifications more or less profound and durable in the entire personality which may be entailed by the diffuse cerebral microtraumatism. The mind gives evidence of mental paresis corresponding to what in the muscles is lax or spastic paralysis, with or without ataxia. There are no hallucinations, no tendency to ataxia; the trouble is in the intelligence and the affections. The anatomic processes responsible for this mental paresis are generally paralleled by changes in the cerebrospinal fluid, an albuminosis with dissociation or inversion of the albumin and cell count. This may subside or last for weeks or months. Toxic-infectious injury of the brain, that is, a chemical lesion of the brain, manifests itself in a set of symptoms of the confusional type. Diffuse traumatic injury of the brain, that is, a mechanical lesion of the brain, manifests itself in the mental processes as a kind of sluggishness in the mind, a mental paresis. An initial loss of consciousness is the rule with this diffuse traumatism from concussion of the brain. When there are localized wounds besides, the set of symptoms from the diffuse concussion and those from the localized trauma should be estimated separately, when they will serve as a guide to treatment, as they explain in detail.

Neo-Arsphenamin in War Surgery.—Bréchet has been giving neo-arsphenamin by the vein after war wounds to ward off or cure septicemia and to aid in the healing of wounds. The action became manifest by the third day and was most marked in acute septicemias without important focal lesions; also, in recent and gangrenous infected wounds of soft parts. No benefit was apparent in massive gangrene and advanced suppurative processes. A single intravenous injection of 0.3 gm. neo-arsphenamin was followed by a surprising change for the better when any effect was apparent. Three typical cases are described.

 Cancer of the Pancreas. M. Loeper.—p. 151.
 Bone Grafts. Barbier.—p. 153.
 Intramuscular Injections of Turpentine. G. Huillet and A. Crémieux.—p. 156.

Cancer of the Pancreas.—Loeper describes the features which distinguish jaundice with cancer of the pancreas from that with gall-stones, especially the large dilatation of the gallbladder testifying to complete obstruction of the common bile duct. This is the rule with cancer of the pancreas but is comparatively rare in cholelithiasis. The stools will decide the question by the high content of nontransformed neutral fats, when compression from the pancreas is responsible for the obstruction of the bile duct. When the obstruction is close to the ampulla of Vater, it is impossible to decide before operating, although an increase in amylase in the blood and urine with its absence from the stools is a sign of obliteration of the pancreatic duct, just as the increase of bile salts in blood and urine and their absence from the stools points to obliteration of the biliary passages.

Bone Grafts.—Barbier makes out the balance sheet for bone grafting operations, the outcome showing there is still much uncertainty in regard to the inner physiology of a bone implant. The balance to date seems to be in favor of living bone for the implant. Conditions are entirely different with dead bone from those with dead nerve implants. Further study of the biology of the bone implant will solve these various problems. Heitz-Boyer has reported twenty-five cases of massive bone implants to correct ankylosis. In the eight aseptic cases success was complete in 75 per cent., as also in 69 per cent. of the seventeen cases in which there was more or less infection. The intervention was a failure in only one case; four are too recent for judgment.

 Gummatous Sporotrichosis. L. Ramend.—p. 160.
 Hot Springs in Treatment of Syphilis. L. Bory.—p. 162.

Sporotrichosis.—Ramond warns that lesions in the form of a gumma in skin, bone or viscus should always suggest the possibility not only of syphilis and tuberculosis but also of sporotrichosis. In a case described, on account of the gummas on the trunk and arms, the man of 57 had been given a course of mercurial treatment but without effect. As intense pains finally developed in the lumbar spine, the diagnosis was changed to tuberculosis, and incipient Pott's disease was suspected. The indolence of the gummas, their rapid development, the absence of fistulas and the arrangement of the gummas along the lymph routes finally corrected the diagnosis to sporotrichosis, confirmed by cultivation of the pus, the macroscopic aspect of the cultures being unmistakable once seen. Agglutination tests, as for typhoid, were still further evidence, sporeagglutination occurring at $\frac{1}{500}$ or $\frac{1}{1000}$. The most conclusive evidence, however, is the rapid retrogression of the lesions under potassium iodid. He gives it by the mouth in a large amount of fluid (beer or Vichy water), beginning with small doses and increasing to a daily dose of 4 gm. Only exceptionally is more than this required, to a maximum of 8 gm. In the case described, the man was unable to bear the iodid by the mouth and it was given by the rectum. When the intolerance is absolute, other iodids should be tried. The earlier this treatment is begun, the more effectual its action, and it should be long continued.

- Gastric Tuberculosis. G. Razzaboni.—p. 153.
 Cicatricial Stenosis of Esophagus. A. Austoni.—p. 161. Conc'h.
 Obstruction of Bile Duct from Cyst. E. Oham.—p. 177.

Gastric Tuberculosis.—Razzaboni gives the microscopic findings in a case of tuberculosis of the stomach in a woman of 60, with complete recovery after subtotal gastrectomy. The symptoms from the stomach had first been noted about two years before the operation. The process was of a neoplastic type along with diffuse inflammatory lesions. When last seen, three years and a half later, she was still well.

Cicatricial Stenosis of the Esophagus.—Austoni discusses the indications in cases of this kind and describes four personal cases. He insists that absolutely impermeable stenosis is extremely rare. It is almost invariably possible to work something through it, and when this can be done, no matter how old or how tight the stenosis, a cure can be counted on by gradual dilatation. This offers less risk and is more certain of a cure than by any other measures. The technic is practically the same as for urethral stenosis; if the stenosis is low down it may be advisable to introduce the bougie through an opening into the stomach. In adults, permanent, interrupted progressive dilatation with the aid of a guiding thread is the simplest means of cure. For children, on the other hand, and for stenosis high in the esophagus, it is more convenient to apply instrumental dilata-

tation, very slowly and progressively, just as for urethral stenosis, and with the same instruments, but proceeding very gradually, not attempting to spread the branches more than 2 or 3 more millimeters at a sitting. Even with intervals of eight or nine days, the course takes less time than with gradual dilatation with bougies. In the two children whose cases are described there were no complications of any kind, and the esophagus had become amply permeable by the end of three months. He gives a preparation of thiosinamin to aid in softening up the tissues, and the effect impressed him very favorably. He gave it even to children in quite large doses at first, about every fifth day, and later, following each dilatation. Guisez advises against this for fear that with the softening of the tissues the tip of the bougie might go astray, but there is no danger of this if the drug is given only after the dilating procedure.

- *Serodiagnosis of Syphilis. A. Scalfritti.—p. 125.

Hysteroid Syndrome.—Ausregillo remarks that up to twelve years ago every case of more or less systematized delirium, with ideas of persecution or grandeur was labeled paranoïa. But now we classify them as paranoïd dementia, etc., and he insists that the same should be done for hysteria. We must classify the cases presenting true hysteria and cases with symptoms resembling those of true hysteria but for which some organic or functional other affection is responsible. He describes six cases to show the necessity for being alert to detect this hysteroid syndrome and to interpret it aright. In two of the cases the course confirmed that the supposed hysteria was incipient dementia praecox. In another case manic-depressive insanity of the melancholia type began with symptoms suggesting hysteria, such as sensory disturbances, anesthesia of eyeballs and pharynx, attenuation of the pharynx reflex, and ideas of negation which suggested simulation, but there were no hysterogenous zones. In another case of apparently typical hysteria, necropsy disclosed a brain tumor. The tendency to a childish point of view was marked in this case, but puerilism is a feature of hysteria as well as of some brain tumor cases. Alcoholism may also induce a hysteroid set of symptoms as in a case described in which hysteria had been diagnosed from the paresthesia, from the *automatismo ambulatorio*, absence of the pharynx reflex, and the occasional hallucinations with a vague persecution tinge, and lapses of memory.

Roentgen Treatment of Uterine Fibroma.—Weil remarks that no one thinks of holding modern surgery responsible for the mishaps before the asepsis era. But many medical men still hold aloof from roentgen treatment of uterine fibromas on account of mishaps they have heard of occurring in the early days of roentgen work. He claims that F. de Courmelles of France was the first to report (Jan. 11, 1904) the application of the roentgen rays in this field, and time has demonstrated the value of cross-fire exposures from a dozen different points more or less. Each field is about 10 cm. and the distance from the anticathode is 20 or 22 cm. at least. He filters through aluminum at least 1 cm. thick, utilizing only the shortest possible waves of the Coolidge tube. His smallest dose is 10 H units of the hardest possible rays, with a 22 or 24 cm. spark. The chromometer gauge is 11 Benoist. He marks each field with a demographic pencil and exposes each field once or twice, going over them all successively on consecutive days. Then he recommences the exposures after an interval of at least a month. The most puzzling problem is when to recommence the exposures. He usually gives four series of exposures, but after the first two he leaves an interval of at least five weeks. The course thus lasts six months, but the menopause becomes installed and the pains much improved during the second month. He cites Pfender's statistics showing that less than 2 per cent. of uterine

fibromas display a tendency to malignancy, while the global mortality from operative treatment of uterine fibromas is at least 5 per cent. He reiterates that roentgen therapy should now be the rule and operations the exception for all uterine fibromas, even the painful and the hemorrhagic ones, except that easily removable pedunculated myomas and those of exceptionally rapid growth should be removed without delay.

The Stomach Mask of Gallstone Disease.—Socca emphasizes that the radiating pain from liver colic may extend to quite a distance, and at some of the remote points thus reached it may set up a set of secondary symptoms which are liable to mask the primary disturbance and mislead the physician. The most frequent and the most dangerous form is when the secondary phenomena occur in the stomach. Even experienced and cautious physicians often yield to suggestion in such cases as readily as a hysterical girl. The patient's statements deal only with the stomach, and his description of his symptoms may fit some well defined stomach affection. In short, Socca reiterates, when confronted with any painful stomach symptoms, do not pay any heed to the stomach until the liver can be definitely excluded. The phrenic and scapular tender points with biliary lesions are often misleading, as also the costal, the shoulder and the pancreaticoduodenal points. The gallbladder may not be tender on superficial examination, but if the finger is dug in deep, and the patient is told to breathe deep, in the midst of the inspiration the patient stops it short and makes an exclamation of pain. Socca calls this the *signo del grifo*, as the patient utters a cry. Another instructive sign is elicited by holding up the liver from below, placing the hand just below the ribs, as the patient takes a deep inspiration. The diseased liver thus is compressed as the diaphragm descends, and an intense pain is felt throughout it. Socca has named this the *signo del torno* as the liver is thus held in a vise, as it were. He illustrates his remarks with numerous instructive case histories. One shows that pain in the scapular region, with nothing to be found in the pleura or lungs, should suggest liver disease. Periodical vomiting first gave the clue in some cases. In one case the liver colic took the form of typical tabetic gastric crises; in other cases the gastric mask simulated nervous motor dyspepsia or the clinical picture of simple gastric or duodenal ulcer. The gastric or duodenal pain of biliary origin may assume the true rhythmic type of simple ulcer for days at a time. Even hematemesis may occur from cholelithiasis alone. One woman of 54 nearly died from the recurring hematemesis but the stomach was found normal and the gallbladder full of stones. Ingestion of bismuth may relieve the gastric pains even when they seem to be due exclusively to the biliary apparatus.

Spontaneous Destruction of Cells in Cerebrospinal Fluids.—Bonahb found in the seventy-four specimens of fluid he examined that the leukocytes became all destroyed in from three to sixty-three days. Even within twenty-four hours the figure dropped from 302 to 6 in one case, regardless of the temperature. This spontaneous destruction seems to be a manifestation of the universal process of autolysis which occurs spontaneously in every organ kept absolutely aseptic, but he found that it could be prevented by changing the reaction of the fluid from alkaline to acid. Addition of 3 drops of acetic acid to each 5 c.c. cerebrospinal fluid has preserved the leukocytes in it in their original numbers and proportions for several months to date in all his tests. It also has a sterilizing action. The hemolysis of the red corpuscles proceeds as usual. Unless this precaution is taken at once after the puncture fluid is obtained, no reliance can be placed on the leukocyte count a few hours later. The amount of this spontaneous destruction varies in different cases. The drop was from 369 to 148 in one case of tuberculous meningitis in twenty-four hours. The details are given of the seventy-four cases and also of thirty-three cases of meningitis in which the leukocytes preserved in the spinal fluid have kept unmodified during the months since.

The Wassermann Reaction.—Scalfritti calls attention to the specific action and always identical constitution of the lipoids obtained with cadmium chloride, especially lipoids from heart tissue, for use in the Wassermann test.

 History of Transfusion of Blood. D. Damico.—p. 323.

Pathogenesis of Cholelithiasis.—Agote emphasizes that while the gallstones develop only in the biliary apparatus, the symptoms from them appear principally in the gastro-intestinal apparatus. Liver colic, with or without obstruction of the bile ducts, is merely an additional episode and does not modify the clinical conception that the manifestations of cholelithiasis are gastro-intestinal on the whole.

Cholesterolemia in Cholelithiasis.—Galindez tabulates the cholesterol content of the blood in large numbers of gallstone cases as well as in other patients. His final conclusions are that hypercholesterolemia is not constant in cholelithiasis, and that there does not seem to be any constant relation between the cholesterol content of the blood and of the bile. The age seems to influence the cholesterol content, possibly from the defective functioning of the endocrine system. His conclusions thus from 153 analyses are directly at variance with those of the French school in regard to the importance of hypercholesterolemia in gallstone disease.

Peptic Ulcers.—Vaccarezza tabulates the details of twenty-seven cases, including one from his own service, in which a peptic ulcer after gastro-enterostomy had entailed a fistula between the jejunum, stomach and colon. Eleven of the twenty-seven patients succumbed to peritonitis; no attempt at operating had been made in three of the fatal cases. In conclusion he recalls that ulcer of the jejunum was known twenty years before gastro-enterostomy was invented. It may occur spontaneously and be a primary lesion. There are cases on record in which the primary operation revealed an ulcer in both stomach and jejunum.

Pott's Disease in Congenital Kyphosis.—Arce and Zorraqum report a case which has broadened their conception of the efficacy of orthopedic treatment of Pott's disease. The kyphosis was of 92 degrees and this was corrected by 44 degrees and the paraplegia subsided. The "Albee implant" was 17 cm. long, with an angle of 136 degrees. The patient was an adult woman, and the seat of the implant showed trophic changes from the extinct tuberculous process. The implant and the technic were all that could be desired but the bed and asepsis were far from perfect. No plaster cast was used, merely four broad strips of adhesive plaster, 3 inches wide, two of them horizontal, two passing from the buttocks like suspenders over the shoulders, to the chest. The transverse strips pass just above and below the hump, and do not meet in front. The cast is illustrated. The kyphosis modified the tuberculous vertebral process so that there was no pain nor stiffness but lax paraplegia developed and an abscess in the psoas. Only staphylococci were found in the abscess.

Regeneration of Peripheral Nerves.—Merzbacher has been continuing his experimental research on the degeneration and regeneration of peripheral nerves, and illustrates some of his specimens. They seem to open a new field for research on means to increase the vitality of a nerve severed from connection with the trunk nerve, so that the peripheral stump escapes degeneration. He accomplished this by placing in contact with the stump triturated brain tissue. This seemed to maintain its vitality and aid materially in its regeneration. The severed and newly sutured peripheral nerve was investigated in a segment of the jugular vein, taken from the same animal, and filled with triturated brain substance. This prevented the formation of a neuroma; the brain substance

showed a tendency to prompt organization and numerous intact cylinder-axes and nerve sheaths were found later in the peripheral stump, demonstrating that part at least had escaped degeneration.

Potassium Cyanid Poisoning.—Damianovich's experiments apparently demonstrate that potassium cyanid forms quite a stable association with blood serum. Certain plant extracts likewise attenuate its activity.

 Diglycidim Parasites of Human Intestine and in Domestic Animals. C. R. L. Neyra.—p. 153.

Syphilitic Liver Disease.—Hernando reports another case in which the symptoms from syphilitic perihepatitis had been ascribed for years to duodenal ulcer or other cause and everything done except the right treatment. The man of 48 recovered almost complete health and returned to business from which he had been debarred by his illness for several years. The first symptoms had been noted twelve years before and the disease had assumed a progressive course after seven years. During these last three years there had been fever, but the symptoms from the stomach, the hyperchlorhydria, the duodenal symptoms had completely misled the diagnosis, notwithstanding brief intermittent jaundice. The ascites had plainly been due to compression from gummata. As these retrogressed under specific treatment, there was no further trouble from this or from the previous intolerable pruritus. The fever for three years had been almost daily and remittent, the temperature normal or subnormal in the morning and running up to 38.1 or 38.6 C., or even higher in the latter part of the day. Hernando is inclined to attribute this fever to the action of the syphilis toxin on the vegetative nervous system.

- *Treatment of Leishmaniasis. F. E. Martinez.—p. 104.
 Generalized Psoriasis. Sicilia.—p. 106.

Treatment of Leishmaniasis.—Martinez has had much experience with kala-azar in children and Oriental sore in adults, and here says that the efficacy of tartar emetic in treatment seems to be now established beyond all doubt. The urine and bowel movements should be supervised. The only mishap in his experience was an attack of severe diarrhea in one case, an actual antimony cholera. The usual dose is 3 cg.

of the tartar emetic, and the intervals between doses are from two to six days. He has found that the preferable method is to have three ampules, two containing each 2 c.c. of physiologic saline; the third ampule contains 3 cg. of the tartar emetic in 1 c.c. of twice distilled water. The injection is made in the vein at the elbow: first one of the ampules of saline, then the ampule of the tartar emetic, concluding by injecting the second ampule of saline. By this means the needle is rinsed out and none of the drug comes in contact with the tissues, as this is liable to induce an abscess. Improvement in kala-azar is evident by the second or third injection; the fever declines and the child recovers its appetite. By the end of the month, recovery is generally complete but he keeps up the injections of the antimony and potassium tartrate for a time.

*Transfusion of Blood after Hematemesis. J. Bejarano.—p. 406.
Treatment of Cerebrospinal Syphilis. E. Campo.—p. 416. Conclusion.

Torsion of Ovarian Cysts.—Fajardo emphasizes that the surgeon should always be prepared for any surprise when confronted with symptoms of torsion of the pedicle of an ovarian cyst. Immediate intervention should be the rule. The clinical picture is often mistaken for appendicitis, but the palpation of a tumor suggests preferably a median incision, as in a successful case described.

Transfusion of Blood.—Bejarano reports that he successfully tided a young woman past the danger of intense anemia from a bleeding gastric ulcer by transfusion of blood from a niece. He reiterates the importance in hospitals of preliminary testing of the blood, and states that the anticoagulating action of the citrate need not be feared in hemorrhagic cases.

*Genital Prolapse at Delivery. J. J. Izquierdo.—p. 230.
Medical Ethics. (La immoralidad médica reciente) S. Ramirez.—p. 230. Concl'n.

Malaria in Mexico.—In this instalment of his article, Torres discusses with thirty-three illustrations the anatomy and biology of the mosquitoes found in Mexico that have been incriminated in the spreading of malaria.

Genital Prolapse at Delivery.—In the case illustrated by Izquierdo, during labor at term the uterus prolapsed suddenly and the vertex of the fetus presented at the os. The fetal heart beat could not be heard and amniotic fluid mixed with meconium was escaping. The rigid cervix seemed to be incapable of dilating further, and he delivered the living child by slitting the anterior cervix for 5 cm. on the median line, two hours after the total prolapse had occurred.

Revista Médica del Rosario

May, 1919, 9, No. 2

José Penna. J. B. Valdés.—p. 112.

*Chronic Intestinal Stasis. L. O. Zeno.—p. 118.

*Serotherapy. Rubén Vila Ortiz.—p. 166.

Megacolon. F. Chiassone.—p. 169.

Chronic Intestinal Stasis.—Zeno has been working with Lane in England and describes with numerous illustrations Lane's theories in regard to chronic intestinal stasis and its causes. He criticizes Lane's ideas, and presents arguments to the effect that the avascular bands are found in the majority of persons, and have no pathologic significance. The same is true of the vascular membrane, Jackson's membrane. This represents relics of the direct prolongation of the great omentum in fetal existence. In studying these bands and membranes we must not be misled by the multiplicity of names that have been conferred on them. The surgeon in particular should familiarize himself with the various aspects which these normal formations may assume. Zeno found the so-called duodenojejunal band in 60 per cent. of forty child cadavers, the ages ranging from 2 months to 10 years. He also noted that when the bismuth suspension reached the

point of the angulation it seemed to slip through the knife as readily as through the wide lumen above. The bands do not always occur at points where they can in any possibility serve as supports, while they may be conspicuous by their absence at other points where they would certainly develop if Lane's theory were sound.

Serotherapy.—Ortiz protests against the custom in Argentina of dispensing antiserums in such small doses that fifty-six vials had to be used, for instance, in one case of tetanus, to give 84,000 units of antiserum. The small number of units per vial renders treatment unnecessarily expensive. He urges that ampules should be available containing 100 c.c. of the antiserum.

Psoriasis in Inherited Syphilis. J. Rosende.—p. 324.

Induced Pneumothorax.—Morelli sketches the history of induced pneumothorax and the experiences in various clinics. He insists that in spite of all the work that has been done, artificial pneumothorax is still in the formative period. Notwithstanding the remarkable results attained with it in some cases, there are still many obscure points in the mechanism of its action and in its applications, as well as inexplicable irregularities in its therapeutic results. By perfecting it further we may be able to multiply the "marvelous resurrections" which have been sometimes realized to date. Strict knowledge of all factors that enter into play in the organism during the application of the procedure will permit a more perfect adaptation of the pneumothorax to the organic conditions of each patient. The question is to obtain the maximum results with the minimum of disturbance.

*Antagonism between Microbes. C. Spada, Jr.—p. 149.

Microbian Antagonisms.—Spada noticed that anthrax infection ran an exceptionally mild course in persons infected with staphylococci. Similar antagonisms between microbial infections has been noticed, he recalls, with malaria and tuberculosis, while malarial subjects are peculiarly susceptible to dysentery and smallpox. On the other hand, the malarial parasites disappear from the blood during intercurrent smallpox and, as Aynaud reports, during grave influenza. Spada's experimental work on guinea-pigs confirmed the attenuation of anthrax infection when the *Staphylococcus aureus* was inoculated subcutaneously along with the anthrax germs. The results were more striking with rabbits; one survived for thirteen days and none died in less than eighty hours. The injected staphylococci induce the formation of an abscess at the point of injection and the accumulation of leukocytes at the point aids in the defense. This assumption was confirmed by the negative results when the inoculation was done by the vein. The five rabbits in this group all died in about two days. Some other experiments were less conclusive, but anthrax bacilli cultivated in vitro with the diplostreptococcus isolated from cases of influenza, seemed to have their virulence utterly annulled.

Tetanus Leg. E. H. van Lier.—p. 1085.

*Contusion of the Pancreas. J. M. van Dam.—p. 1091.

Metastasis with Cancer.—De Vries found cancer at 518 of 3,700 necropsies, and he here discusses the metastases found with them, and the frequency and distribution with different

types and locations of the cancers, and compares his findings with those on record. The liver cancers entailed metastasis in a surprisingly large proportion of the cases, and lung cancers in a surprisingly small proportion. The metastatic lumps are also at correspondingly opposite extremes in size with lung and liver cancers. He was impressed further with the frequency of metastases in bones, 53 out of the 518 cases, and the whole of the skeleton was not examined so that other instances of this may have escaped detection. In some cases there were multiple metastases in the skeleton, suggesting a blood-borne origin. Metastasis in the skeleton was noted in 7 of the 19 cases of mammary cancer and in 5 of the 19 cases of prostate cancer. There were only 2 cases of thyroid cancer in his material, but in one of these there was metastasis in the skeleton. The metastases develop readily also in the suprarenals and ovaries, but not in the spleen, heart and muscles. In 69 cases of cancer in the esophagus, metastasis occurred in the liver in 26 per cent., the larger proportion with low seated cancer. The longer survival with the latter may explain this. Mechanical factors alone are unable to explain metastasis with malignant disease, especially the preference for certain organs. The size of the cancer cells does not explain this either. Cancer cells probably circulate freely in the blood stream but die off readily. Chemical factors may aid in their destruction in certain organs in which metastasis seems to occur rarely. This suggests the possibility of treating cancer with extracts of these organs. Attempts in this line with spleen tissue and extract have given negative results to date as far as he knows. In Kaufmann's 1,078 cases of cancer (Basel) there was metastasis in the spleen in 8; in these the primary lesion was in the uterus, penis, thyroid, kidney, gallbladder or stomach. In Mielecki's 487 cases the frequency of metastasis in the skeleton with mammary and prostate cancer was as marked as in De Vries' Amsterdam cases (8 in 18 and 11 in 30). Comparison with other statistics confirms the greater prevalence of primary cancer of the thyroid in Switzerland, and of the lungs at Berlin, but with all the statistics the percentage of organs affected with metastasis is proportionately about the same. The fact that metastasis is so rare with cancers in the larynx and upper esophagus may be explained by the comparatively early fatal termination. The exemption of the muscles from metastasis, the exemption of the brain from metastasis with gastric cancer (no signs of metastasis in the brain in Kaufmann's 227 cases of gastric cancer and only in one of Mielecki's 156 cases), and the predilection of the liver, skeleton and suprarenals to metastasis are insoluble mysteries at present.

The Fear of Cachexia Thyroprivia.—Lanz emphasizes that surgical relief is imperative when a person with goiter has a hoarse voice, an aphonic cough, stridor or difficulty in inspiration when climbing stairs. Indications for operative measures are still more common with toxic disturbances, hyperthyreosis or dysthyreosis, and if sufficient of the excessively functioning gland is removed, he declares, a complete cure may be counted on even in extreme cases of exophthalmic goiter. General practitioners do not realize the full efficacy of operative treatment in such cases, while they have an exaggerated dread of cachexia thyroprivia. They do not realize that surgery has progressed far beyond the point of operations which permitted this to develop. Surgeons are able now to discriminate and to spare sound thyroid tissue, but general practitioners are still advising their exophthalmic goiter patients against an operation. Lanz reiterates that nowadays there is no reason for this; the collar incision leaves only an amotetecal scar; part of the capsule is left, thus precluding injury of the recurrent nerve; the parathyroids are not molested and hence there is no danger of tetany, while enough thyroid tissue is always left so that cachexia thyroprivia is no longer encountered. Notwithstanding all this, surgeons still hear the same old story, "My doctor says this is a very dangerous operation," or "My doctor told me that this operation would make me an idiot." Even on the operating table, the question comes, "Are you sure that I won't turn into an idiot?" The trachea flattened by the goiter will resume its shape when the pressure has been removed, and the toxic symptoms will subside when the

poison-generating tissue is no longer there to cause trouble. Practitioners generally should appreciate this, and should overcome their misplaced fear of cachexia thyroprivia.

Contusion of the Pancreas.—In van Dam's case the contusion was from the horn of a bull and the young man died about a month later, the pancreatic duct having been lacerated. The condition at first did not seem serious but laparotomy the third day showed the escape of pancreatic juice into the abdominal cavity through the foramen of Winslow, and into the bursa omentalis. Notwithstanding thorough drainage, symptoms of ileus developed and the man died the day after entero-anastomosis. Van Dam has found twenty-five cases on record of isolated open injury of the pancreas and sixty-two of isolated contusion of the pancreas. Trauma seems to be an important factor in the development of cystic disease of the pancreas.

*Roentgen Therapy of Cancer. T. Eiken.—p. 641.

Roentgen Therapy of Cancer.—Eiken reports from Rosing's private clinic the complete cure of a woman of 46 who in the course of fifteen months had had a mammary carcinoma removed and also two recurrences at its site, and during the last six months had been having pains in the femur on that side, and a large metastatic tumor developed here. This tumor subsided completely under vigorous roentgen treatment. The pains were relieved after the first application (30 H. through 6 mm. aluminum), and by the end of the month she could take a few steps without support. The results were as complete as with excision of the focus, but this treatment, as too often happens, was not applied until the malignant disease had invaded practically the whole body, and the patient succumbed to metastasis elsewhere. In another case a large mammary cancer subsided to a clinical cure under one exposure (50 H. 8 mm. aluminum, ninety minutes) with a second exposure after a month's interval. All his other patients succumbed sooner or later to metastases probably already installed.

*Gastric Achylia; Treatment with Hydrochloric Acid. V. Bie.—p. 825.

Gastric Achylia; Treatment with Hydrochloric Acid.—Bie reports a case of gastric achylia with enteritis and anemia for many years, refractory to all treatment. The patient was a physician of 34, and Bie treated him with hydrochloric acid in doses large enough to supply the proper proportion for normal digestion. He gave at first 1 c.c. in 250 c.c. water once a day, increasing this gradually to 5 c.c. in 250 c.c. water and keeping up this dose at intervals for nearly three months. The acid was administered through a stomach tube, 6 mm. in diameter. The effect on the enteritis was prompt and decisive, and by the fourth month the patient had recovered his strength and was able to resume his practice. There was no doubt that the cure of the enteritis and the anemia was the result of the hydrochloric acid treatment, administered in doses larger than are usually given. In conclusion, Bie remarks that the advantage of kefir treatment in pernicious anemia may be due to the lactic acid in it which supplies the lacking acid in the stomach to a certain extent. It might be feasible to give hydrochloric acid with it. This treatment is not suited, of course, for all cases of gastric achylia, just as kefir has not always a favorable action in pernicious anemia. It might be advisable to give it a trial at least in every case. He tabulates the dates of the treatment in his case. The hydrochloric acid was not given every day, only nine times in the first month and six times in the second month, the doses ranging from 1 to 8 c.c. of the acid in from 250 to 500 c.c. of water. The aim was to provide the acid in the same amount and fluid contents as in the natural reaction. The stomach secretes a 4 or 5 per thousand solution of the acid which corresponds to a dilution of the hydrochloric acid of the pharmacy of about 1:50. The acid was given fasting once a day.

SPIRIT OF THE PHYSICIAN IN WAR AND PEACE*

WILLIAM M. BEACH, M.D.
PITTSBURGH

Students of enterology today have behind them two decades of organized effort replete with valuable research and knowledge of disease in this line of medical and surgical endeavor; so that when our efforts were sufficiently recognized as a section in the greatest medical organization in the world, our programs and discussions reflected the wisdom of the departure.

Responsibility was no doubt keenly felt this year by officers of all the sections, since we were in the throes of war and not a few of our leaders were in commission to serve the nation. The programs, however, have proved our misgivings unfounded.

What a year this has been! A year of swift, startling, far-reaching changes; a year that brought the great war to a climax and then, with a sweep and a rush, to its close; a year when the cause of freedom and justice and humanity touched the lowest depths of doubt and reached the highest pitch of triumph; the most decisive and dramatic year in modern history. This year is a record of the life and work of this section during these critical twelve months. It shows how we have played our part; and we have a right to be thankful rather than ashamed, as we look over the record. This section could have a service flag that would stand for real service. Our men have been in the fighting line and in the base hospitals. We can point with pride to Harris, Hirschman, Pilcher, Hanes, Graham, Lyon, Lynch and others who have served the nation with devotion. We welcome your return. Those of us who have remained at home have steadily served the same great cause. Our regular work has been maintained, substantially unimpaired, often at the cost of greatly increased labor on the part of a depleted corps of workers. It has been a year of good service and hard work, richly worth while. Of our section it may be said, "Their line has gone out through all the earth." This being a victory year, your chairman thought it appropriate to speak briefly of our profession in war and peace.

HEROISM OF PHYSICIANS IN WAR

Accustomed to service in civil life, the physician, with little or no persuasion, enlisted in the war activities of the nation enthusiastically and with the sacrificial spirit. He frequently sacrificed the large emolu-

ments of civil practice and position for the modest compensation offered by the government, eschewing all thought of rank as a reward, but with an altruism imbued with the idea of doing his bit to make the world a decent place in which to live. He accepted the challenge of war. Thus, the war emphasized in the physician anew the spirit of sympathy and courage.

Having made the initial sacrifice of leaving home and practice, he is preeminently fitted to sympathize with and relieve the suffering of the nation's defenders. We read of the rare courage frequently evinced by the army surgeon, under clandestine attack, while performing his duty, not only in the advanced stations but also in the base hospitals. Forgetful of self, his high purpose to relieve the stricken soldier was executed with a will that neutralized a sense of danger, and led him into the conflict with a heroism well nigh transcendental.

But war and the excitement of battle give immunity from much pain, because one is buoyed by the glamour and the excitement of conflict coupled with the supreme thought of doing something worth while for humanity. This state of mind is the basis of true heroism, and is shared alike by the physician and the soldier; besides, their relations as medical officer and patient melt in the crucible of sympathy, merging into the higher relationship of brotherhood. As our illustrious President has said on occasion:

The sympathy that has the slightest touch of condescension in it has no touch of helpfulness about it. If you are aware of stooping to help a man, you cannot help him. You must realize that he stands on the same earth with yourself and has a heart like your own, and that you are helping him, standing on that common level and using that common impulse of humanity.

The men on this program who have served the colors are able to relate first-hand experiences that are thrilling, for they have been in contact with the ebbing lives of thousands who made the supreme sacrifice; yet the service in ministrations of surgical relief does not attract the crowds, or win their acclamations in the same degree that they are vouchsafed to the commanding general, whose business is to kill. The physician is not a killer, but a saver of life. The altruism of the age is well illustrated in the physician in civil life and in times of peace. The doctrine of service never was better exemplified in the world than by the medical profession today. Why are physicians not as enthusiastically received as would be as many military captains of high renown? Simply because the idea of service is not yet comprehended; simply because the older trade of taking life still holds more glamour than the newer one of saving life.

Physicians are not inferior in heroism, personally or as a class, to the soldiers of the world. They take

* Chairman's address, read before the Section on Gastroenterology and Proctology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

more chances in their everyday practice than ever a general officer of an army encounters. The sacrifice of life and health made by the modern physician, in his work for humanity, are not less real, only less dramatic, than the sacrifice in war.

General Pershing said of the physicians in the army:

Many of them have shared with the line troops the hardships of campaign conditions, and have sustained casualties and privations with fortitude that is beyond praise. No labor has been too exhausting and no danger too great to prevent their full discharge of duty.

REWARDS IN THE SERVICE

The physician will come into his own. His heroism will get its reward, for, in the final test, men will give all they have for health. The most remarkable developments of medicine and surgery are sealed books to the public. They are not translatable into the vernacular. But more remarkable still than all the improvements in surgery, the roentgen ray, and all the germ-fighting discoveries, is this vastly greater and more comforting discovery of the spirit of service in the profession itself.

Not all physicians accepted in the service received the same rank (it was impossible that they should), nor was the distinguished service cross pinned to every breast that deserved one. Some may have received them without having fully earned them. But, be that as it may, every medical officer deserving special distinction will be rewarded by his inner consciousness of having given the best that was in him for his country. The great mobilization of the times graciously included in its plan a neatly executed certificate for those of us who were just as patriotic, but who were unfortunately born too early to meet the age requirements.

PROGRESS THROUGH RESEARCH

To approach the highest efficiency in his ministrations in war and peace, the physician must have the spirit of research.

Knowledge and skill are needed in addition to sympathy and sacrifice. Not content with his attainments in civil practice, he willingly doffed civilian garb and donned the military, to become a part of the organized and disciplined bodies and souls of men whose achievements are objects of the nation's acclamation.

The physician who is wholly bound by tradition is a failure. His profession requires the open-minded, inquiring and adventurous spirit which makes for progress. With these facts in view, thousands of the guild, regardless of position or attainment in civil life, assumed the rôle of pupils and sat at the feet of instructors chosen by the government to direct their energies in military channels. The procedure was not easy either for the government or for the new medical officer, since it involved the law of selection as to the adaptability and the fitness of the applicant for new and responsible duties. The results reflected the wisdom of the authorities who established the training camps for the army surgeon in the making.

The camp was in effect a postgraduate school, wherein the physician was standardized both mentally and physically and in the art of medicine and surgery. He was given a new vision and enthusiasm. He was drilled in surgical technique to the minutest detail. He was taught to command, to know his place, and to have proper respect for authority, as well as to command respect for himself.

Fortunate is he whose personality passed through this ordeal, for it has evolved the new physician, better equipped for the era of peace now dawning. He has emerged with higher attainments and greater experience than he could ever have enjoyed otherwise, which fit him for leadership in medical thought and practice. He will reflect the new standards in peace times that will inure to the advantage of the men who remained at home, as well as of the general public. But we must not be satisfied, on the other hand, to linger with these achievements, but must use them as stepping stones toward a higher goal; for "Art is long, time fleeting, and judgment difficult."

Modern medicine has evolved from an art of observation and empiricism, approaching an applied science based on research, divorcing itself from the cobwebs of tradition and sagacity and substituting therefor analysis and law.

THE SPIRITUAL ELEMENT IN TREATMENT

Proficiency in the physician requires development in the direction of spirituality.

It is not enough to make research into the material factors in recovery. There is a curative force which is moral and spiritual, an intimation of which is seen in the cult of Aesculapius, of whom the gods were jealous because of his acquirements in the use of hidden forces in the healing art, a rediscovered truth in modern days.

Medical science should not become wholly materialistic, since our knowledge is applied to a composite entity which is moral and spiritual as well as physical. Nor is it well to divorce these higher forces from the physical.

The good physician sets in motion the obscure and subtle forces which play on the sensibilities of the patient. He himself radiates health of body and of mind, and cooperates with the experts in the realm of the spirit.

CONCLUSION

The battle with the sword has been fought. Peace once more hovers over the earth. Nations again will direct their energies in the channels of trade, arts and science, and industrial life. The lessons of cooperation learned in war will be projected into civil life, ushering nations and individuals into a new era fraught with new problems and new relationships.

The spirit of the physician in this new age must be alert and able to interpret the stately steppings of progress, in order that his guild may keep abreast of the times with the other lines of activity. We must meet the challenge of peace as well as that of war.

901 Bessemer Building.

Is Your Community Fit?—Do you know how many of the registrants from your community were rejected by the medical examining boards as unfit for military duty on account of tuberculosis? Has a campaign for the relief and prevention of tuberculosis been organized? If not, as a minimum requirement, provision should be made for the proper reporting of all cases of tuberculosis and for health instruction of families and patients, especially in families where there is a patient with advanced disease. Where the patient requires hospital care, is provision made for such care, either through city institutions or by arrangement for bed space in state or district tuberculosis hospitals? It is highly desirable to provide special clinics for the diagnosis and care of cases of tuberculosis before the disease has progressed too far.—*Pub. Health Rep.*, April 25, 1919.

THE TREATMENT OF GAS BACILLUS
INFECTION*

FREDERICK T. VAN BEUREN, JR., M.D.

NEW YORK

Statistics in regard to gas bacillus infection are relatively rare. It has been possible to gather only a few, yet those few seem to reveal that both its morbidity and mortality lessened very appreciably in the latter years of the great war. I dare only say "seem to reveal," for the reports are both fragmentary and occasionally contradictory. I have selected the following as those most fairly comparable regarding morbidity, mutilation and mortality.

MORBIDITY

Early in 1916, Gross¹ had 2,796 wounded men pass through his ambulance, of whom 101 (3.6 per cent.) developed gas gangrene. In late 1916 the same man treated 1,676 wounded men,² thirty-three of whom (1.9 per cent.) developed gas gangrene. In October, 1918, Sienr and Mercier³ reported that fewer than 0.5 per cent. of the wounded developed gas gangrene in the advanced and intermediate zone.

MORTALITY

Lardenois,⁴ in 1916, reported 500 cases of gas bacillus infection with 15 per cent. mortality; and Ivens,⁵ in 1917, 460 cases with 9.5 per cent. mortality.

Regarding definite gas gangrene, as distinguished from gas bacillus infection in general, Gross, in 1916, listed 101 cases with 56.5 per cent. mortality, while Ivens, in 1917, reported 107 cases with a mortality of 26.4 per cent. It must be emphasized here, however, that of the cases reported by Gross, those which were treated within twelve hours after the wound was received had a mortality of only 10.9 per cent. This indicates more clearly than any description could the importance of early treatment.

MUTILATIONS AND MORTALITY

In 1916, Gross reported seventy-two amputations (71.3 per cent.) among his 101 cases of gas gangrene, with a mortality of 52.7 per cent. following amputation, while, in 1917, Ivens reported sixty-five amputations (60.7 per cent.) among his 107 cases, with a mortality of 26.2 per cent.

Is it fair to believe, then, that even before serotherapy was added to operation, some improvement had been shown in the results obtained by surgical treatment? I think that perhaps it is.

Let us now examine the later reports, made after the serologic work of Leclainche and Vallée,⁶ Sacqué-

pée,⁷ Weinberg,⁸ Bull and Pritchett⁹ and others had begun to be applied in war wounds infected with the gas bacillus. Again the reports are comparatively few, and generally of a small series of cases. In 1917, Duval and Vaucher¹⁰ reported fifty instances in which a combination antiperfringens, antiedematiens and antivibrio septicum serum prepared by Weinberg and Séguin, was injected prophylactically.

In none of the patients did gas gangrene develop, although all were of the most severely wounded type. Twenty-five died as a result of severe multiple wounds without any signs or symptoms of gas bacillus infection.

In 1918, the same authors¹¹ reported 281 cases in which severely wounded patients were injected with serum from the Pasteur Institute, a pooled serum of antiperfringens, antiedematiens, and antivibrio septicum. Eighteen cases of gas gangrene developed (6.4 per cent.), resulting in ten deaths, so that the mortality rate of 3.5 per cent. thus established, after prophylactic injection, was lower than that which these authors call the usual mortality rate from gas gangrene (16 per cent.) among those severely wounded.

Mairesse and Regnier,¹² in the same year, reported that of 1,016 wounded men examined bacteriologically, 297 showed gas bacillus infection. These were given prophylactic injections of antigangrenous serum, either antiperfringens, antivibrio septicum or antiedematiens, as required by the bacteriologic report. In thirty instances, 10 per cent. of the cases, gas gangrene developed.

As regards mutilation, Ivens,¹³ in October, 1918, using the triple serum of Weinberg and Séguin reported 222 cases in which use was made of the prophylactic injection, and among which no deaths resulted from gas gangrene, and fourteen amputations for gas gangrene without a fatality. In 154 other instances he gave a prophylactic injection of the Leclainche and Vallée polyvalent serum. There were fifteen cases of amputation for gas gangrene among these. Four patients died, a mortality of 26.6 per cent. In fifty-seven other cases, injections of both Weinberg and Séguin's and Leclainche and Vallée's serum were given. In ten of these, gas bacillus infection was already evident; but in the whole series of fifty-seven there were only two deaths (3.5 per cent. of the whole number, or 20 per cent. of those with evident infection at the time of injection).

Marquis and others,¹⁴ in 1918, reported fifteen cases in which prophylactic injections were employed, and in none of which did gas gangrene develop.

Referring to mortality, Duval and Vaucher,¹¹ in 1918, reported seventy-seven cases of gas gangrene in which the patients were given curative injections. Sixteen died (20.7 per cent.). There were only eight amputations in this series, with no resulting deaths. Marquis and others,¹² in the same year, reported ten cases of gas gangrene in which curative injections were used. Two patients, whose second dose had been delayed, died, a mortality of 20 per cent.

Rouvillois, Guillaume, Louis, Pedeprade and Thibierge,¹³ late in 1918, reported twenty-five cases in which curative injections were employed. Six patients, of whom three were already moribund, died, so that the mortality was from 12 to 24 per cent., according as one views it.

Maisse and Regnier,¹² in the same year, gave curative injections in thirty cases, with a mortality of 16.6 per cent. If we compare the lowest mortality from gas gangrene treated by operation alone (23.4 per cent.) with the average mortality of cases treated by operation plus serotherapy (18.3 per cent. of a total 142 cases given curative injections) we find the latter to be somewhat lower.

CAUSES OF LATER IMPROVEMENT

There are a number of factors which may be responsible for the lower incidence of, and lessened mortality from, gas bacillus infection in the latter part of the war. For example, the ground on and in which the soldiers fought had not received its annual bath of manure for some time. Then, too, the weather was far less severe in 1918 than in the preceding year. Doubtless, also, the camp, field and trench hygiene was better regulated, and facilities for bodily cleanliness and garment renovation had been widened. But of all activities the bettered effectiveness of which increased the wounded man's chance of recovery, rapid transportation holds, perhaps, the premier place. So startling is the difference between the mortality percentage of those men operated on early and those operated on late, that I think we can agree to give rapid transportation of the wounded soldier to the hospital, where he can properly be operated on, an important place under the broad heading of the treatment of gas bacillus infection.

Earlier diagnosis of cases developed in the hospitals came with greater experience in the symptoms of the disease, and brought with it earlier operation and improvement in the operative results. Better fixation of fractures, especially lower extremity fractures, lessened the laceration of tissue and, consequently, the susceptibility to infection. Experience taught that the prolonged application of tourniquets was dangerous, and greater precautions were taken in their sometimes necessary use. Clothing fragments and rough missiles came to be recognized as the infection carriers, and an attempt at their careful removal became routine practice.

It is easy now, in the light of four years experience, to give a moderately adequate reply to the primary question, "What have we here to treat?" But, in the early part of the war, there was a complete, though a natural, ignorance, as a consequence of inexperience, that required time to be supplanted by education. Surgeons began by simple incisions and drainage. They

tried out many more or less fantastic methods that the active imaginations of certain praiseworthy enthusiasts had advocated, and arrived with rather creditable rapidity, I think, at the fairly standardized procedure which obtained later on among those who had been well taught. But, as inexperience must still exist today among many who had not the good fortune to participate in the overseas surgery, let us answer our own question and, in the answer, find the modern treatment of gas bacillus infection.

PROBLEMS OF THE PATIENT AND THE INFECTION

We have, then, the problems of the patient, of his environment and of his infection to consider. I will dodge the question of environment by reiterating the importance of such predisposing factors as bad weather, contaminated soil, dirty skin and clothing, poor sanitation, rough missiles, and prolonged exposure before, and slow transportation after, wounding, a few of which are partially under practical human control. As for the patient, his general and local conditions are, of course, interdependent, but for the sake of clearness must be considered separately. He is often in a condition of shock, more or less profound. He may have been partially starved or dehydrated, as well as chilled and severely bled. If his infection has already developed, he is suffering from toxemia and acidemia. He is like a man on a balanced plank, with one end over a bottomless abyss. Remove some of the weight at his end of it, and he walks to safety; add to it, and he slips off, irrecoverably lost. No one but God or experience can give the good judgment required of a surgeon in deciding what and how much operative interference such a patient will stand, and when he will stand it best. The instructed shock team man will tell you that there is a peak in the curve of many a doubtful case at or near which whatever operation is to be made ought to be performed. Nothing takes the place of operation in this disease-injury complex, and it is probable that nothing ever will. For we have to meet not only the toxemia, which may be combated by serum, and the acidemia, which is correctable by alkalization, but the local condition as well, a condition of wide tissue destruction and rapidly spreading infectious process.

Gas bacillus infection can, of course, occur in any wound; but it is almost invariably in severe wounds that it does occur, and particularly in those of the lower extremity, associated with fracture, vascular injury and muscle damage. Such a wound is always far larger beneath than in the skin, and of surprising irregularity. Its depths hide one or more rough missiles and bits of clothing or equipment. Its crevices are filled with blood clots, large and small, and it is walled by muscle, fascia and aponeurosis, shockingly torn, contused and loaded with indriven fragments of comminuted bone and with extravasated blood.

The regional blood supply is locally or massively interfered with by pressure obliteration, or by tearing of the vessels with thrombosis.

Even if it is sterile, such a wound presents many dangers and difficulties. But added to devitalized tissue and blood clot we have infection, usually with a varied flora, particularly the gasogenic, saprophytic anaerobes. No matter what variety of anaerobic saprophyte it may be, here we have all the conditions necessary for its rapid and successful growth: warmth, moisture, darkness, abundance of suitable nourish-

11. Rouvillois, Guillaume, Louis, Pedeprade and Thibierge: *Traité de Gasogenèse*. (Lancette) by Autogangreneux. Sémin. Biol. et méd. Soc. le char de Paris. 11: 1226, 1918; *Abstr. Surg., Gynec. & Obst.*, Int. Abstr. Surg. 28: 63 (Jan.) 1919.

ment, and a minimum of oxygen admissible from air or blood supply. It is no wonder that the gas infection runs up within a damaged muscle sheath like flame up a flue, and follows the vessel sheaths and blood-filled intermuscular spaces as a river follows its banks.

TREATMENT

Once the general and local condition of the patient is well understood, the principles of the treatment inevitably suggest themselves: shock treatment by heat; detoxication by serum; alkalization by intravenous injection of sodium bicarbonate; removal of all dead tissue, infectious agents and foreign bodies by operation; and assurance against further tissue injury or infection by splints, dressings and Carrel treatment. But while these principles are sufficiently simple, the method and the extent of their application in the individual case are to be weighed always in the judgment of the individual operator; and only general rules for operation can be given.

1. Operate as early as possible.
2. Use nitrous oxid-oxygen anesthesia if possible.
3. Prepare the part with the minimum amount of delay and trauma.
4. Avoid tourniquets.
5. Make incisions longitudinally and half again as long as you think they need be, both in skin and fascia.
6. Leave as much skin as you dare, in your débridement.
7. Go between, rather than through, normal muscles, and do not cut across them unless you have to (better a long separation between two than a short cut across one).
8. But open the wound as thoroughly and freely as you possibly can.
9. Excise all torn, crushed, discolored, noncontractile muscle, until you have left only that which is firm, of normal color, actively contractile, and which bleeds readily.
10. Make a careful and conscientious search for and remove all loose bone and foreign bodies, especially clothing and blood clots.
11. Stop the bleeding; leave the wound wide open, and separate its walls with wet gauze, laid in, not packed in.
12. Use Carrel tubes, if you know they will be properly cared for. Otherwise omit them.
13. Use plenty of dressings and make careful splint fixation of the part.
14. Do it all as rapidly as you possibly can.

These, in substance, were the instructions given us when we started in, back of the Château Thierry business, last July, and I have found little to add to them from the literature. One may excise a part or the whole of a muscle, or of a group of muscles, or one may have to amputate; but the principle remains the same and the limitation of its application continues always a matter for one's own judgment.

Carrel-Dakin instillation is very generally agreed on as the best postoperative local accessory, when properly used. Wright's hypertonic salt and other solutions have been proved less successful. Nacciarone's¹⁶ multiple deep incisions with iodine irrigation would have to be seen to be judged fairly. I confess that the abstracted reports of it do not impress me as convincing.

SEROTHERAPY

Serotherapy remains to be considered, and in that I have had no personal experience, as we had no anti-gas serum in any of the seven different advanced hos-

pitals to which our team was assigned. Every one, however, who has been interested in this subject has heard or read of the serum work of Leclainche and Vallée,⁶ Weinberg, Sacquépée,⁷ and Bull and Pritchett.⁹

In a general way, it may be said that while serotherapy promises much for the future, it has not had much opportunity for performance in the past; or, if it has had, the reports are not yet available. A brief search of the recent literature netted a few reports, some of which I have already quoted; but the reports of the large series of cases in which serotherapy was tried out by the British last spring, and that of the smaller series in which it was tried by the Americans last autumn, I have been unable to secure, and can submit only a general brief of them as given me in a personal communication from Lieut.-Col. William Elser of our Medical Corps.

In the spring of 1918, the British made a considerable test of serotherapy, using a weak, polyvalent serum containing antitoxin against *B. welchii*, *B. edematiens*, *Vibrio septique* and *B. tetani*. Prophylactic doses were given to 15,000 soldiers; 15,000 controls were selected, and records were kept of those developing gas gangrene in both groups. Week by week, as the reports came in, it appeared for some time as if a success were to be scored for serotherapy. But, when all the reports were in, both those of the controls and those of the group given prophylactic treatment, a careful review showed that there was not sufficient difference in the incidence rate to warrant any definite declaration as to the protective value of the serum used. Apparently, however, the investigators were favorably impressed; for they laid the failure to secure positive results to the weakness of the serum that was then available.

Early in the spring of 1918, bacteriologists who had been working in France on the gas bacillus infection problem were sent back to the United States to start the manufacture, on a considerable scale, of antigan-grenous serums. Several serums were planned, (1) an antiwelch, (2) an antiedematis, (3) an antivibrio septique, and (4) a polyvalent combination against these three organisms. All were to be secured from animals immune to tetanus.

For several reasons the manufacture progressed slowly; but, in the fall of 1918, about 5,000 doses of serum reached the central laboratories of the American Expeditionary Forces, and preparations were made to test it in the wounded. Because conditions of weather and soil, the type of projectile and the elapsed time after wounding all act as modifying factors in the incidence of gas gangrene in wounds, controls were selected from the same groups of wounded (and on the same days) as those to whom the antiserum was administered. In all, about 2,500 were treated and 2,500 controls selected in October, 1918. It must be remembered that the injections, to be administered early, had to be given as near the front as possible, sometimes under fire, and that intravenous administration was out of the question. They were, therefore, injected into the deep muscles, if possible, or subcutaneously; and, when time and place permitted, into the region of the principal wound. On the whole, the results were encouraging, and it is believed that if the armistice had not interrupted the progress of the test, a very favorable report might finally have been rendered, which would have dictated the employment, as a routine measure, of the antigas

¹⁶ Nacciarone, A.: Gas Gangrene and Phlegmons, *Riforma med.* 23: 772 (July 21) 1917; *Abstr. Surg., Gynec. & Obst., Int. Abstr. Surg.* 69: 1119 (Sept. 29) 1917.

serum in that great spring drive of 1919 for which our armies were then preparing.

Dr. Elser advises the following routine for the serum treatment:

1. A prophylactic dose of polyvalent serum, given as early as possible after the receipt of the wound, combined with tetanus antitoxin.

2. Bacteriologic examination of the wound and establishment of the presence of gas bacillus infection and determination of the variety of the bacteria. The determination can be made in about twenty-four hours.

3. Administration of specific serum, either single or polyvalent or "pooled," according as there are one or more gas formers found and also anti-treptococcus serum.

It is emphasized that serotherapy is entirely auxiliary and in no way replaces operative treatment of the wounds. Quénu, for example, in advocating the use of Leclainche and Vallée polyvalent serum, declares that "the mechanical early and complete clearance of the wound is essential to success," while Rouvillois and others,¹² using antivibron septique and antibellonensis serum, "practice the surgical technic exactly as if there were no question of serotherapy." And Marquis¹⁴ concludes that, "although curative serotherapy assures recovery in the great majority of cases, it is only an aid to the necessary surgery."

In November, 1917, the third Interallied Surgical Congress for the Study of War Wounds¹⁷ reported that antiperfringens serum seemed to have given favorable results as a preventive injection, and that the antivibron septique and antiedematisans serum had given very appreciable results, both from a preventive and a curative standpoint. In November, 1918, the same conservative body announced¹⁸ that preventive serotherapy in the French Army had reduced the frequency of gas gangrene, and that curative serotherapy had given equally encouraging results. But they added that these should never be regarded as more than an adjuvant to surgery which, as they put it, "is still indicated and in no way modified". The specificity of antibodies, of course, complicates the problem. It is like a lock which can be opened only by one key, and consequently the administration of the serum in its preventive and its curative uses must be governed accordingly. Since any of the three common organisms, *B. perfringens*, *Vibron septique*, or *B. edematisans*, may be the infecting agent, a polyvalent or pooled serum must be used preventively, unless early bacteriologic examination has identified the bacteria present. But, in curative therapy, on the other hand, in which there is always time for the identification of the infecting agent, the specific antiserum or antisera are preferably employed.

The various reports generally agree that intravenous injection (while not always possible) is to be preferred, in combination with deep muscular injection, proximal to, but in the vicinity of, the wound. Ivens¹² diluted the serum and gave it subcutaneously for fear of the so-called "anaphylactic shock." But, as comparatively few instances of this have been observed to occur, the later practice tends to concentrated serum and larger doses. Sacquépée¹⁹ used from

40 to 80 c.c. of each serum (antivibron septique and antibellonensis), injecting half into the muscles near the wound and half subcutaneously, at a distance from it, in preventive therapy; and repeated the administration after twelve hours. For curative purposes, he used (in the edematous form) 80 c.c. of antibellonensis (half subcutaneously and half intravenously) and 20 c.c. of antivibron septique, subcutaneously, the injection repeated in from four to six hours, and again in from sixteen to twenty hours. In the gaseous form of the disease he used from 30 to 50 c.c. of each serum, half intravenously and half subcutaneously.

Duval and Vaucher¹⁰ gave a preventive injection of from 30 to 100 c.c. of triple or pooled serums, prepared by Weinberg and Séguin, injecting it as early as possible (within six hours of wounding) into the muscles above the wound, and advised its administration at the triage.

Ivens,¹² in his most successful series, used an initial preventive dose of 10 c.c. Leclainche and Vallée polyvalent serum, with 30 c.c. of Weinberg and Séguin's triple mixed serums, and followed it up repeatedly if symptoms developed.

The Rouvillois group,¹³ following Sacquépée, used the antivibron and antibellonensis serums in doses a little smaller than Sacquépée and repeated them daily in toxic cases.

Maireisse and Regnier,¹² after establishing by bacteriologic examination the presence of *B. perfringens* in their wounded men, gave an immediate preventive injection of from 20 to 40 c.c. of antiperfringens serum. *Vibron septique* or *B. edematisans* was found in the wounds of twenty-five of these men, as well as *B. perfringens*. From 10 to 20 c.c. of the proper antiserum as well as of the antiperfringens serum were given in these cases. Those whose wounds developed gas gangrene were given secondary doses of serum, varying from 80 to 100 c.c.

Marquis¹⁴ gave a preventive injection, into the muscles, of antivibron septique and antibellonensis (20 c.c. of each), if the time was within ten hours of wounding. Patients seen later received 40 c.c. of each. The larger doses were repeated, after twelve hours, in those cases which clinically appeared infected.

The curative doses he gave were intravenous, 60 c.c. of antibellonensis and 20 of antivibron septique, repeated after six hours and again in twenty-four hours, followed by daily injections of 20 c.c.

The encouraging results of the later work incline one to feel that future improvement in the results of treatment for gas bacillus infection will rest on preventive and curative serotherapy, as well as on observance of the correct operative procedure and on earlier operation.

Personality of the Physician.—The personal character and habits of the physician are only second in importance to intellectual ability and professional training. The physician should be well mannered, discreet and of good repute; wise in judgment, temperate and self-controlled. Honorable in all his dealings, he should unite firmness with gentleness and should avoid luxury and display, frivolity and levity. He should not be greedy of gain, but should accommodate his fees to the circumstances of his patient, and, if necessary, render his services gratuitously. He should think more of his honor than of profit, and rather run the risk of incurring the ingratitude of a patient he has treated than add to the distress of a sick person by bargaining about fees during illness.—Tweedy, *Brit. M. J.* 2:598 (May 17), 1919.

THE BASAL METABOLISM AND HYPERGLYCEMIC TESTS OF HYPERTHYROIDISM

WITH SPECIAL REFERENCE TO MILD AND LATENT CASES *

G. W. McCASKEY, A.M., M.D.

Professor of Medicine, Indiana University School of Medicine
FORT WAYNE, IND.

A recent writer¹ has remarked that our position in the study of thyroid disease is about what it would be in regard to diabetes if we were without our laboratory data relative to the urine and the blood. It is well known² that in some very severe cases of thyrotoxicosis the thyroid gland is not definitely palpable, or at most not more so than in very many presumably healthy persons. This emphasizes the fundamental importance, if any emphasis were needed, of looking beyond the goiter for clinical data more distinctive and more strongly diagnostic than the clinical signs and symptoms usually present in thyroid intoxication.

Recent observations have confirmed the suspicion long entertained that other endocrine glands besides the thyroid play a more or less important rôle in exophthalmic goiter. This is especially true with reference to the thymus, the importance of which would almost seem to justify the term "thyroid-thymus syndrome" for this condition. Whether or not this term is too cumbersome, or possibly might too much exaggerate the relative importance of the thymus, it reflects a point of view which needs emphasis at the present time. For instance, Blackford and Freligh,³ on the basis of seventy-four necropsies, conclude that an enlarged thymus is present in 100 per cent. of patients under 40 years of age, and in about 50 per cent. of those above 40, in whom the average weight of the thymus was 1.3 gm. Matti⁴ says that the monopoly enjoyed by the thyroid in exophthalmic goiter is at an end. Halsted⁵ on the basis of a very large experience concludes that the important rôle played by the thymus in exophthalmic goiter is demonstrated beyond question by animal experimentation, and especially by the cures resulting from primary thymectomy and also from secondary thymectomy following thyroidectomy which alone had been unsuccessful.

There are two pressing needs in the study of thyroid disease. The first of these is the differential diagnosis of the so-called borderline cases and the determination of the toxicity of an existing definite goiter. Practically all cases of thyroid disease belong to this group at the outset for a variable period, which may be very short or very long—may in fact be measured by days or by years. A group of more or less vague symptoms, which might be either constant or intermittent, and consisting for the most part of tachycar-

dia, nervousness, and hyperidrosis, and a trifle later varying grades of debility and digestive disorders, and perhaps a little later still, mild, irregular febrile disturbances, formed the basis of the clinical diagnosis. These symptoms are, obviously, the expression of a toxemia with somewhat variable group reactions, and which may in many cases easily be due to any one of several different causes, and especially chronic infections.

The second pressing need is something besides the subjective sensations of the patient and the ordinary clinical manifestations, to enable us more accurately to measure the actual rise and fall of the thyrotoxic state, just as by the rise and fall of hyperglycemia and glycosuria in diabetes we follow the course of that disease. Owing to the neuropsychopathic character of so many of these thyrotoxic patients, it is essential that it should be objective in its nature. In my opinion the recent clinical application of the basal metabolism and alimentary hyperglycemia tests has very satisfactorily met these demands and marks an epoch in the study of hyperthyroidism.

BASAL METABOLISM

We will first consider the basal metabolism which is by far the more important of these two methods. By basal metabolism is meant that minimal quantity of metabolic change essential to the neuromuscular and secretory phenomena of what might be called the basal and necessarily continuous organic functions—respiration, circulation and secretion. Rest and food abstinence approximately eliminate all other metabolic activities. It has been well known since the classical work of Friedrich Müller⁶ and Magnus-Levy,⁷ about twenty-five years ago, that one of the most characteristic phenomena of hyperthyroidism was an increase in general metabolism, while hypothyroidism produced exactly the opposite result. This, of course, depends on the regulatory action of the thyroid secretion on metabolic processes, which apparently bear a direct relationship to each other. It is perfectly evident, therefore, that the optimum conditions of body function are dependent on a definite quantity of thyroid and synergistic secretions which can only vary within narrow limits without producing more or less serious disturbance.

Since that time a great deal of work has been done by various investigators in confirmation and elaboration of these facts. This work has for the most part been done in well-equipped hospitals and institutions with large and complicated apparatus requiring, for instance, the services of an expert gas analyst and, therefore, not at all practical for general clinical purposes. Taking advantage of the fact that heat production could be measured equally well if not more accurately by oxygen consumption alone than by direct calorimetry, Dr. F. G. Benedict⁸ has devised a portable and comparatively inexpensive apparatus which can be operated in any small hospital or office by any one reasonably familiar with laboratory technique. The introduction of this apparatus, which can be placed in the corner of any convenient room, the only accessory being a couch, places the entire medical profes-

sion under additional obligation to this distinguished investigator.⁹

The estimation of metabolism by measuring the units of heat production is made possible by the application of Rubner's law, that it is proportional to the body surface from which, with some exceptions, all heat not actually expended in energy production is radiated. The basis of this law is, of course, the universally accepted laws of the conservation and

Chart 1.—Basal metabolism in actual and suspected hyperthyroidism.

transmutation of energy and the radiation of heat. The chemical forces of the body, which represent the sum total of metabolism, are transmuted into heat, the excess of which over body requirements is radiated from the surface. The standard chosen is the number of calories per square meter of body surface per hour. The body surface is determined very simply by what is known as the "height-weight formula" based on two factors: namely, the height in centimeters and the weight in kilograms. By the use of the chart, plotted from this formula, as worked out by Du Bois,¹⁰ and the two factors of weight and height, the body surface expressed in square meters is instantly read without any calculation whatever. In the determination of oxygen consumption the patient is made to fast overnight and then to lie on a couch for thirty minutes or more to get rid of the respirable products of all metabolism other than basal, resulting especially from the voluntary musculature. The patient breathes through the mouth-piece connected with the open air for a few minutes in order to establish quiet normal breathing, after which the breathing is in and out of a spirometer bell. The oxygen and nitrogen are rebreathed, for the carbonic acid is entirely removed from the expired air by being passed through an absorbent (soda-lime). The scale on the side of the spirometer bell is read at the beginning of the observation and again at the end of whatever period is chosen (usually ten minutes), both observations being made at the same point of time; that is, at the end of expiration. Since the carbonic acid gas has disappeared

and the nitrogen is not influenced, the difference in the readings on the spirometer scale accurately represent the amount of oxygen consumed. The volume of gas is then corrected for barometric pressure and thermometer readings in order to bring it to the standard of sea-level and zero centigrade. This corrected volume which is obtained by the use of logarithms, but which could undoubtedly be determined on the percentage basis with sufficient accuracy for all clinical purposes, is used as the basis of the indirect calorimetric calculation. Each liter of oxygen gas, with the above mentioned corrections, represents 4.825 calories of heat. From this the calories are calculated for one hour. By dividing the calories per hour by the body surface, determined as above indicated, we have the final result of calories per square meter per hour.

The number of calories per square meter of body surface per hour varies normally with sex and age and perhaps other physiologic conditions. By the Du Bois or "height-weight" formula, the average figure for men is 39.7; for women, 36.9. In pathologic conditions and conspicuously in disturbances of thyroid secretion, these figures are subject to numerous variations. In hyperthyroidism the increase is striking; very mild cases, including the borderline group, and frank cases of thyrotoxicosis in the quiescent state, may show an increase up to 30 per cent.; mild cases, 30 to 50 per cent.; severe cases, 50 to 75 per cent., and very severe cases, 75 to 100 per cent. or more, following the classification of Du Bois excepting that the "mild" cases of Du Bois (below 50 per cent. increase of basal metabolisms) are subdivided into "mild" and "very mild" to correspond with his "severe" and "very severe" cases above 50 per cent. increase.

Table 1 and Chart 1 illustrate the range of cases studied and give the general grouping of the cases. Perhaps the most important feature is the relatively large proportion of cases belonging to the mild and very mild or borderline group. As indicated above, the main purpose of this clinical study was the differential diagnosis and positive identification of the cases in this group, which frequently cannot be done by the ordinary clinical methods. There will be found, with some exceptions, a striking parallelism between the percentage increase of basal metabolism and the relative intensity of the thyrotoxicosis. This parallelism

9. Dr. Janney of New York, in his discussion of this paper raised a question which I overlooked in the closing discussion, and which I think deserves attention. He said that the metabolism observation even with the Benedict portable respiration apparatus was not easy. Certainly it is not easy. The greatest care and accuracy are required. For example, if the patient after resting half an hour should, without the knowledge of the clinician, arise from the couch and walk, say 20 feet, and close a window, it would raise basal metabolism about 15 per cent. If the metabolism observation was made after instead of before the 100 gm. of glucose in the technic described in this paper, this would cause an increase of 5 per cent. The slightest error in measuring or in the duration of the observation, or escape of air or oxygen around the mouth piece, would introduce substantial error. A failure to correct volume of oxygen to zero C. and sea-level barometric pressure, if such an oversight were conceivable, would make another increase of from 1 to 15 per cent. It will thus be readily seen that if careless or incompetent work should find its way into literature, under a mistaken impression of the simplicity of this procedure, it would be very deplorable.

10. Dr. Boes, DeLorand, and Du Bois, E. F.: A Formula to Estimate the Approximate Surface Area of Height and Weight Be Known, Arch. Int. Med. 17: 863 (June) 1916.

is so close that the percentage increase of the basal metabolism seems to serve as a reliable guide in the classification of the cases and an accurate measure of the fluctuations that may occur either spontaneously or as a result of treatment.

In the study of basal metabolism it is important to remember that like all physiologic processes in either normal or pathologic conditions, it is subject to marked variations. This variation, however, offers no greater difficulties here than in other procedures, such as the

Chart 2.—Simple curves illustrating types of alimentary hyperglycemia in thirty-one cases of hyperthyroidism: A, blood sugar fasting; B, blood sugar one hour after 100 gm. of glucose; C, blood sugar two hours after 100 gm. of glucose.

tests for albuminuria, glycosuria, the Wassermann test, variations in temperature, etc. When properly correlated with the general clinical syndrome it may be regarded as one of the most reliable and scientifically accurate aids available in any field of diagnosis, and is of inestimable value not only in establishing the diagnosis but in studying the clinical course of this disease.

ALIMENTARY HYPERGLYCEMIA

The occurrence of alimentary hyperglycemia in hyperthyroidism has been known since the work of Tachau¹¹ in 1911. At that time and until quite recently, the methods of blood analysis were too cumbersome for clinical use. The recent investigations of Lewis and Benedict,¹² Myers and Bailey,¹³ and others, however, placed this work on an entirely different and clinically practical basis, and stimulated both experimental and clinical investigations along this line. With the aid of these very simple and accurate colorimetric methods the entire subject of blood sugar content has been worked over afresh within the last few years.

Living in a thyroid zone and confronted almost daily by the diagnostic difficulties above mentioned, I was attracted by the method described in the paper by Denis, Aub, and Minot.¹⁴ This method seemed entirely practical. The test, as outlined by them, can be completed in a little more than two hours, or if immediately preceded by the basal metabolism observation, which is my method of choice, the entire procedure will require less than three hours, most of this time being spent in waiting.

The fasting blood is first taken; then the patient is given 100 gm. of glucose. In one hour a second blood specimen is taken, and in another hour a third, which by this technic completes the blood study. The urine

also is examined at the end of the first and second hours, and may be examined for several hours longer, although the glycosuria is a question involving the renal glucose threshold rather than the thyroid question.

Under normal conditions, in the average person in the fasting state, 100 gm. of glucose does not produce a hyperglycemia lasting as long as one hour. At least, this was the result in fourteen of my own cases, and in sixteen of those recorded by Denis, Aub, and Minot.¹⁴ Hamman and Hirschman,¹⁵ however, obtained an alimentary hyperglycemia in normal persons following 100 gm. of glucose, the crest of the wave occurring in from twenty to forty minutes but still remaining to some extent at the end of one hour or longer. In view of these facts, it must be regarded as possible that a transient hyperglycemia occurred during the first hour in observations made according to the methods used in this paper, disappearing at the end of the first hour.

Whatever may be the fact in regard to normal persons, there seems to be no question that in hyperthyroidism after the ingestion of 100 gm. of glucose there is almost invariably a marked hyperglycemia, the crest of the wave occurring at the end of the first hour, or at least recognized then by this method, with a sharp fall in 70 per cent. of my cases by the end of the second hour. This curve was found in twenty-two of thirty-one cases (about 70 per cent.) of hyperthyroidism. In six cases (20 per cent.) the hyperglycemia continued to rise until the end of the second hour. In three cases only (or about 10 per cent.) the hyperglycemia did not occur until the end of the second hour. These curves are represented graphically in Chart 2, based on Tables 3 and 4. The delayed hyperglycemia shown by the curves represented in Types 2 and 3 is probably the result of retarded absorption

* Cases 128 and 127 show an absolute hyperglycemia, but it will be noted that the fasting blood sugar is quite high, raising a question of an associated pathology.

due to gastro-intestinal conditions. It suggests the possibility of a delayed hyperglycemia occurring in some of the cases in which it does not appear within the two hour period. This is apparently a valid criticism of this technic. My answer is that in the forty-five cases of actual or suspected hyperthyroidism forming the basis of this section of this paper, there were thirteen (Table 2) which did not show a hyperglycemia within two hours, and in none of these could the diagnosis of hyperthyroidism be established on other grounds, although two or three still look suspicious.

In practically every case in which the diagnosis of hyperthyroidism seemed to be reasonably well established on other grounds, including the basal metabolism observations, a definite hyperglycemia occurred not later than the second hour, and in 90 per cent. of the cases within the first hour. As a routine procedure, therefore, I believe that the two hour period is sufficient.

In doubtful cases, and especially when the determination of basal metabolism might be made, the alimentary hyperglycemia test, as above outlined, may prove to be of considerable value. Of course diabetes, alcoholism, etc.,¹⁶ must be excluded.

SUMMARY

The differential diagnosis of many mild, atypical or very early cases of thyrotoxicosis by means of the ordinary clinical signs and symptoms can only be made with varying degrees of probability. The need is, therefore, very great for definite objective data, either decisive or very strongly corroborative, not only to determine diagnosis, but to estimate therapeutic results. The clinical application of basal metabolism and alimentary hyperglycemia satisfies these demands in a very scientific, practical and satisfactory manner.

Basal metabolism, or the metabolism of the fasting body in the resting state, can be quickly and accurately determined by measuring the oxygen consumption with the Benedict portable respiration apparatus. The average normal heat production, which is an accurate index of metabolism, is about 39.7 calories for men and 36.9 for women by the "height-weight" formula per square meter per hour under the conditions indicated. Physiologic variations of not more than 10 per cent., and nearly always much less than this, may occur in either direction.

Maximum increase, 33%.

In hyperthyroidism there is an increase up to 100 per cent. or more, according to the severity of the intoxication, which varies in different cases, and in the same case at different times.

In hyperthyroidism there is a diminished tolerance of carbohydrates with alimentary hyperglycemia, and also with glycosuria whenever the hyperglycemia exceeds the renal glucose threshold of the individual patient.

16. In view of Pemberton's very valuable contribution made at this session, we must add arthritis to the list, and further studies may possibly add still more. The alimentary hyperglycemia test can only be regarded, then, as confirmatory, our main reliance being placed on basal metabolism.

In every case of hyperthyroidism studied (thirty-one cases) the blood sugar content was increased within two hours from 50 to 200 per cent.

In 70 per cent. of thirty-one cases the maximal rise occurred at the end of the first hour, with a more or less sharp decline at the end of the second hour, proving that the crest had been reached and passed.

The very few cases in which hyperglycemia is highest at the second hour may be explained by gastric hypomotility and slow intestinal absorption.

Postoperative

The failure of the hyperglycemia to rise proportionately to the increased metabolism and to bear any direct relationship to the intensity of the thyrotoxicosis suggests that it is an indirect phenomenon due perhaps to overexcitation of other organs, for example, the pancreas, which in exceptional cases fails to respond to the thyroid stimulation.

The application of these tests will probably reveal a much greater incidence of hyperthyroidism than has formerly been recognized, and will especially enable us to make a clear diagnosis between toxic and nontoxic goiters. While a final diagnosis is altogether a question of clinical judgment, and should not be made exclusively in the laboratory; and while neither increased metabolism nor alimentary hyperglycemia is pathognomonic of hyperthyroidism, yet, when rationally correlated with the remaining clinical data, they together make as clear-cut a diagnosis of hyperthyroidism as a positive Wassermann does of syphilis in a suspected case.

ABSTRACT OF DISCUSSION

DR. JOHN C. HEMMERT, Baltimore: It is a great pleasure to listen to a paper that aims to have physiologic facts for its foundations. Dr. McCaskey's aim is simply to afford a new and practical method of diagnosis in doubtful cases of diseases of the thyroid. He assumes that the processes of oxidation in hyperthyroidism are increased and that there is a hyperglycemia two hours after 100 gm. of glucose are injected into the circulation and that this hyperglycemia is pathognomonic. I have seen the apparatus Dr. McCaskey employed for the respiring of a measured amount of oxygen by a resting subject. I saw no means for the absorption of the humidity that the patient himself gives off to the expired air. It makes a good deal of difference in the carbon dioxide absorbed by lime and the patient's own humidity. If it increases that of the respired gas to 80 it will increase the percentage of blood sugar by 13 per cent. of the normal. I would suggest some provision to account for this change in the blood sugar due to the humidity gradually accumulating in the spirometer, i. e., if the expired air actually reenters the spirometer. I do not wish to go through all the argu-

ments of sugar metabolism from Claude Bernard, Pavy and Otto Colnheim and our own men down to Folin, Frederick M. Allen and others, but I hold that when you inject 100 gm. of sugar into an individual, a hyperglycemia two hours thereafter is physiologic. Therefore the method requires revision and further investigation. H. J. Hamburger (Groningen, Holland) in the most recent investigations which have come to me in the last ten days is opposed to this view of colloidal blood sugar. He says that all sugar when injected into the animals that have a separate circulation in the glomeruli from that of the renal tubules, as in the frog, behaves like sodium chloride, and he gives further evidence that sugar exists in the blood just like sodium chloride—not in combination. Postprandial hyperglycemia can be found in 90 per cent. of normal people. That there is an excess of blood sugar that can be caused by injecting 100 gm. of dextrose directly into the circulation can be ascertained by using several of the most modern methods for blood sugar determination. The whole matter has been gone over by McCleod in his recent book on biologic chemistry as applied to medicine. The excessive oxidation in hyperthyroidism appears to be well established by many biochemists. But in this very fact when associated with hyperglycemia we have a paradox and that paradox is one of the most puzzling things in medicine. Here we have a furnace that will burn anthracite coal and refuses to burn paper although you blow in pure oxygen. Of all the foods the carbohydrate molecule is the easiest to split up under above conditions, and the organization splits up the protein molecule, the most difficult, and even oxidizes the carbohydrate molecule moiety of the protein molecule. It reminds one of a simile from a verse in the "Ancient Mariner"—"Water, water, every where, nor any drop to drink"—"Sugar, sugar every where, and not a milligram to oxidize."

DR. LEWELLYS F. BARKER, Baltimore: These two tests—that for measuring basal metabolism and that for measuring the glucose content of the blood—are certainly valuable tests in clinical diagnosis, especially for deciding upon the existence of what we call "overactivity of the thyroid gland." The methods, to the uninitiated, sound complex. They are, in reality, fairly easy to perform; and it is interesting that clinical men have devised simple modes of making measurements that formerly involved a very complicated technique. The basal metabolism is certainly increased in severe forms of exophthalmic goiter, and the sugar content of the blood, also, seems to be increased. Dr. Hemmeyer has suggested that the existence of a hyperglycemia implies a state in which the body cannot split the carbohydrate molecule. May it not rather be simply that the sugar molecule, in some states at least, is mobilized more quickly than under normal conditions. For if the body, in the state under consideration, can split, as he says, the protein molecule and can burn the carbohydrate moiety of this protein molecule, why should it not be able, in the same state, to split the sugar molecule itself. The hyperglycemia might then be looked upon as the result, merely, of a sudden and rapid mobilization of sugar. Whether the increased basal metabolism and the hyperglycemia are due to the direct action of thyroid products, or are indirect results of thyroid activity, remains to be seen. We must think of the influence of the thyroid products on the cell metabolism all over the body, on the one hand; and, on the other, we must keep in mind the influence of the thyroid products on the activity of the other endocrine glands. I would mention one relationship, especially that of the thyroid to the suprarenal gland. Many of the phenomena that we speak of as hyperthyroidism may, in reality, be due to hypersuprarenalism, and it may be that some of our clinical tests for thyroid activity measure directly rather the suprarenal activity, and only indirectly the thyroid influence. I simply point out some of the difficulties, though I think that the tests are really valuable in internal medicine and I hope that they will be much more employed, and that we may come to some agreement as to what the results they yield may mean.

DR. NELSON W. JANNEY, New York: With regard to the blood sugar tolerance test it has been the experience of myself and co-workers that by standardizing the technique it

is possible to get more definite and accurate results than previously obtained. We now give, as already reported, 1.50 gm. sugar dissolved in 25 c.c. of water per kilogram of the patient's body weight, adding the juice of one lemon for flavoring. The fasting blood sugar value is obtained immediately before and one and two hours after taking the sugar lemonade. We thus find the normal blood sugar level to run from 0.12 to 0.14 per cent. without glycosuria. I wish to call attention to a very important point not yet presented in this discussion, namely a criticism of the value of the blood glucose tolerance test in diagnosis. Its value in this respect is problematical for myself and others have repeatedly observed abnormally high blood sugar curves in various conditions, i. e., pituitary disorders, Addison's disease, and other less clearly defined endocrinopathies. Unfortunately, therefore, this test, though frequently indicating an abnormal carbohydrate metabolism in hyperthyroidism, is by no means pathognomonic of that condition. We should, I feel, await with caution and patience more extended observations in this most interesting field.

DR. GEORGE W. McCASKEY, Fort Wayne, Ind.: In regard to Dr. Hemmeyer's remarks, no matter whose figures he quotes, 0.3 per cent. as the normal blood sugar has certainly been discredited entirely. This figure was obtained by imperfect methods in use at that time. It has only been possible in the last few years by the use of the colorimeter to clinically determine the blood sugar content accurately. I believe we can do it now very closely. As to the factor of humidity in metabolism observations, I am not a physician, but have made all the corrections indicated by Dr. Benedict. The fact that in forty-five consecutive cases the fasting blood sugar content is about what it ought to be, shows that there was no gross error, and even admitting any error, this error will be the same in both fasting and alimentary glycemie test, and that is all that is really necessary for the purposes of this clinical study, as it makes the comparative values reliable. Dr. Barker, I think, hit the nail on the head when he said that the hyperglycemia is not directly caused by the thyroid excess. I believe that the thyroid with other synergistic members of the endocrine system may modify other functions, such as the internal secretion of the pancreas, or the glycogenic or storage function of the liver, and in that way account for changes in blood sugar content. It is not simply a question of oxidation. It may be, among other things, mobilization, as Dr. Barker said. A failure on the part of the storage function of the liver or the voluntary musculature may account for the hyperglycemia. Dr. Jamey's criticism that a certain amount of glucose should be given per kilogram of body weight is well taken and is probably important. As a matter of fact, however, it did not seem to modify clinical results. Dr. Geyelin found glycosuria when the glucose intake exceeded 1.8 gm. per kilogram of body weight per hour. This is not a thyroid question at all, but a question of the renal glucose threshold, which Denis, Aub and Minot have established at about 0.17 or 0.18 per cent. blood sugar. Undoubtedly the scientific way to do this is to give a certain amount of sugar per kilogram of body weight, although in none of my thirteen normal cases did a hyperglycemia occur with a uniform intake of 100 gm. of glucose irrespective of body weight, unless the fasting blood sugar was already high. This is probably best accounted for by the enormous reserve function which apparently enables a patient weighing, say one hundred pounds, to promptly metabolize 100 gm. of glucose as readily as a patient weighing 150 pounds. It is perfectly obvious that if the glucose were increased, a point would be reached at which one patient could metabolize it and the other could not.

War Diet and Diabetes.—Bouchardat in France and Klemperer in Germany, reported at the time of the Franco-Prussian war in 1870, that under the dietetic restrictions entailed by the war, the course of diabetes was as a rule less severe. Elias and Singer have recently published similar observations. In the *Wiener klinische Wochenschrift* they state that classifying their cases by age and grade and comparing the course before and since the war began, demonstrate an unmistakably favorable influence from the war diet.

COMPATIBILITY OF LONG LIFE WITH
LOW RENAL FUNCTION *

JAMES P. O'HARE, M.D.

BOSTON

It is customary to consider chronic nephritis as a steadily progressive, degenerative process. As a rule, we do not think of the possibility of a stay in its progress when the disease has reached an advanced stage. One would certainly predict in such a case that the duration of life, with renal function near zero, must be extremely short. And yet, at the Peter Bent Brigham Hospital we have observed several patients who have lived for three or four years with such a low renal function. I wish here to report two such cases.

In the time allotted, no complete study or detailed description of the cases is possible. In order to tell as much as possible I have tried to make the chart self-explanatory.

Chart I.—Case 1: *Syst.*, systolic blood pressure; *Diast.*, diastolic blood pressure; *CO₂*, bicarbonate combining power of the plasma; *Cr.*, creatinin of the blood; *Phthal.*, phenolsulphophthalein excretion; *N. P. N.*, nonprotein nitrogen of the blood; *Cl.*, or *BL Cl.*, blood chlorid; *B. U. N.*, blood urea nitrogen.

REPORT OF CASES

CASE 1.—A girl who, at 9, had scarlet fever without known sequelae; at 18 and 19 had a severe anemia necessitating her being in bed for three months and one month, respectively. In view of subsequent events I think we can fairly assume that our patient had an unrecognized acute nephritis following her scarlet fever, and at 18 and 19, acute exacerbations of a chronic nephritis. So far as we could learn, there was no other possible etiology.

About this time she began to develop vascular symptoms which took the following forms: spasmodic blurring of sight; cramps in legs and fingers, and occasional dizzy spells. Morning headaches then began to appear with increasing frequency, severity and duration. In addition there were occasional drowsy spells. Apart from the latter, our patient's symptoms had been entirely vascular and not at all renal. At the age

of 23 (in May, 1915) she entered the hospital for her headaches.

Physical examination at that time revealed a moderate secondary anemia; a normal heart; no evident sclerosis of peripheral or retinal vessels; a blood pressure of 165–110; no edema, and negative eye grounds.

The urine was of low gravity, and contained a slight trace of albumin, but no casts. (It is important to note that at no time during our three and one-quarter years of observation did the urine show any sign of an active degeneration in the kidney. Hyaline casts even were very rare.) The phenolsulphophthalein excretion was only 12 per cent., instead of the normal 60 to 80 per cent. The blood urea nitrogen was 59 mg. per hundred c.c., about four times the normal. The renal test did showed a marked inability on the part of the kidneys to handle water, salt and nitrogen.

During the patient's six weeks' stay in the hospital, her general condition improved, the headaches were relieved, and the blood pressure fell to normal. Her renal condition, as far as we could measure it, did not change.

It would seem fair to conclude that the vascular condition with intermittent hypertension was responsible for the chief symptom—headache—and that at this time the kidneys, though markedly sclerosed, were giving her comparatively little trouble in spite of their low function. I do not believe, however, that any of us felt at the time that the patient would live for three and one-quarter years with such a low renal function.

In the sixteen months previous to her second entry in November, 1916, the patient was fairly well. Her headaches, however, returned; nose-bleeds were common, and there was an occasional drowsy spell. Her symptoms were still largely vascular. She came back to the hospital chiefly for study.

This showed the following changes: (1) definite cardiac hypertrophy; (2) a return to her hypertension; (3) some sclerosis of the retinal arteries (though none could be detected in the radials and brachials), and (4) a few white spots (probably degenerative) in the retina. The urine and all of the functional tests were identical with those at the previous entry. There was no evidence of active renal degeneration, and renal function was near the minimum.

It would seem fair to conclude that the vascular disease was progressing with an effect on the heart and retina but no measurable change in the kidneys.

During 1917 the patient was not seen, but was apparently very well except for her headaches. She went about, took long walks, danced, etc. In December she had the grip, apparently without much effect. In February, 1918, she had

an attack suggesting renal colic with hematuria. About the first of April she caught a severe cold, which was followed by a very severe headache, vomiting, much blurring of vision and edema of face, neck and upper sternum.

At entrance this time she showed the following new findings: (1) the tender edema mentioned above; (2) a heart of the same size but with more signs of hypertrophy; (3) definitely palpable radials; (4) greater sclerosis of retinal arteries with small hemorrhages in each eye; (5) a higher blood pressure, 190 and 120; (6) the phenolsulphophthalein excretion had dropped to 0, where it stayed until her death, eight months later, and her blood urea nitrogen had climbed to 98 mg.

In the hospital she began to improve rapidly. Her blood pressure began to fall. She then developed an acute infection of the antrum, and with this went immediately into uremia with drowsiness, twitching, two severe convulsions and coma. Her blood pressure did not rise and soon after showed a fall to a very low normal. There was a marked acidosis, the blood carbon dioxide reaching a level of 16 mm. The blood urea nitrogen rose rapidly to 168 and the blood chlorid fell from

* From the medical clinic of the Peter Bent Brigham Hospital.

* Read before the Section on Practice of Medicine at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

in January, 1908, when he was 62 years old. He had a "bad cold" followed by swelling of his eyes and face. He was in bed intermittently for eight weeks, part of the time in the Boston City Hospital. Here the records showed albuminuria and hematuria. About the first of June the edema had increased, and there were dyspnea and orthopnea. This necessitated his entry into the Massachusetts General Hospital, where he stayed for two weeks. The diagnosis of sub-acute glomerulonephritis, ascites, double hydrothorax and cirrhosis was made. The urine showed a large trace of albumin, a few hyaline and granular casts, and a moderate number of red and white cells. The blood pressure, determined for the first time, was found to be 150.

The patient was not seen again for three years, but was apparently well until just before his next visit to the Massachusetts General Hospital in October, 1911. At this time the diagnosis was chronic nephritis and cardiac decompensation. His urine still showed signs of some renal activity. His blood pressure, as can be seen on the chart, had increased to 190—125. The first phenolsulphonphthalein test showed an excretion of 17 per cent. in one hour.

The patient was seen a few times in the outpatient department of the Massachusetts General Hospital in 1911 and 1913. In 1914 he had a flareup of his nephritis following an acute diarrhea.

Shortly afterward, in April, 1914, he first entered the Brigham Hospital (Chart 2). His condition was very poor. There was an acute exacerbation of his nephritis, and uremia was impending. He was stuporous, drowsy, nauseated and had headaches. His blood pressure was over 200. His phenolsulphonphthalein excretion was 0, and his nonprotein nitrogen climbed to 130 mg. per hundred c.c., about five times its average amount. Furthermore, his added urea and salt test showed marked inability to handle these two substances.

The outlook with such findings was without doubt grave. Certainly one could not expect him to live five more years, as he did.

He was seen a few times in 1914 in the outdoor department for headache, weakness, dyspnea and drowsiness. In March, 1915, he entered our hospital a second time for these symptoms. He seemed to be in a state of low grade uremia. His urine was about the same, except that there was no activity. His blood pressure was still over 200, but rather promptly fell to normal, as can be seen on the chart. The phenolsulphonphthalein had improved a bit, but was still extremely low (13 per cent.). The blood urea nitrogen was over 60 mg. Without doubt, at this time the patient's kidneys were markedly sclerosed.

He appeared at the outdoor department occasionally during 1916, 1917 and early 1918. During this time his urine showed but slight activity. His pressure varied from 225 to 160 systolic, with the diastolic more steady around 100. The phenolsulphonphthalein excretion was only once as high as 14 per cent., and the blood urea nitrogen was between 40 and 60 mg. In the early part of 1918, a two-hour renal test showed a marked fixation of all elements.

In April, 1918, he entered the Brigham Hospital the third time for slight toxic symptoms. He was not very sick and his stay was short. His urine showed no change. His blood pressure had dropped to nearly normal, his phenolsulphonphthalein and blood urea nitrogen were about the same as before. He returned in June for two weeks because of a "convulsion" and great drowsiness. There was little new, however, to be found. His urine was no different. His blood pressure was a little higher, around 175.

In September of that year he was admitted for the fifth time for severe dyspnea, palpitation and occasional twitching. The dyspnea was due to a chest full of fluid and was relieved by tapping. His blood pressure was again over 200, his phenolsulphonphthalein practically 0, and the blood urea nitrogen between 40 and 50 mg.

Between the fifth and last entries there was nothing especially new except that his heart began to give more trouble, with occasional sudden dyspnea and tightness in his chest. In November, definite alteration of the pulse was noted.

Dec. 21, 1918, he entered for the sixth time, because of precordial distress. He did not seem awfully sick but quickly

became more and more drowsy. His respirations grew gradually slower and deeper. He became irrational, semiconscious and finally comatose. Twitching of hands, feet and mouth occurred, but no convulsions. There was anuria for three days. In the meantime the blood pressure dropped, as it frequently does before death. A marked acidosis developed, the blood urea nitrogen mounted quickly to 200 mg. and the phenolsulphonphthalein was, of course, 0.

At necropsy the kidneys were very small (62 and 70 gm.) red and granular. The cortex measured only 2 to 3 mm. The renal artery and larger branches were not abnormal. Microscopically, however, the vessels within the kidney showed marked arteriosclerotic changes. Many of them showed all stages of obliteration. There was very little kidney parenchyma left. The intact glomeruli were extremely scarce. Many showed recent infarction from thrombosis of the vessels leading to them. Tubules had disappeared in great numbers. Those that were left showed degeneration of all kinds. The connective tissue was particularly prominent.

COMMENT

Here, then, is a case of chronic nephritis which, starting apparently with an acute process in 1908, had active flareups during 1911 and 1914. By the latter year the process was a very severe one with the function of the kidney practically nil. After that the activity of the degenerative process was comparatively slight.

I want especially to call attention to the fact that during these five years the phenolsulphonphthalein excretion was never over 14 per cent., and most of the time much nearer 0, and that the blood urea nitrogen was consistently four or five times the average normal.

It is difficult to determine just why this patient survived for five years with such an extremely low function. In contrast to life carefully regulated life of the first patient, who lived within the low level set by her renal function, this patient did everything that a renal patient should not do—at least up to 1917. He was just a tramp, who ate whatever he could get and, before 1918, drank heavily. He was, however, surprisingly free from infections which might break down what little functioning tissue remained. One must conclude that the small amount of renal tissue which the patient had during the last five years was sufficient to keep him alive until the vascular disease within the kidneys had progressed to such an extent that in the last few weeks many of the small vessels became thrombosed, and with this the glomeruli supplied were put out of commission.

These two cases, then, demonstrate the possibility of prolonged existence with an exceedingly small amount of renal tissue and an extremely low renal function. The only possible explanation is that the disease during this time was a purely vascular one. The pneumonia played directly or indirectly an important part in the death of the first patient. The thrombotic obliteration of essential glomeruli was responsible for that of the second.

It can hardly be said that the true prognosis was in any way indicated by the tests performed.

536 Commonwealth Avenue.

ABSTRACT OF DISCUSSION

DR. HERMAN O. MOSENFELDER, New York: The cases Dr. O'Hare described are of great interest and importance. He made mention of the fact that most of us would not have expected these patients to live as long as they did and I believe we can readily agree with that statement. The problem before us is to find out what factors determine the

prognosis in nephritis and to apply this knowledge in the treatment of our patients. The expectancy of life of the sufferer with chronic nephritis may be regarded as being measured by three possible terminations: First, factors which may be considered to be entirely extrarenal, of which heart failure, apoplexy and intercurrent infections constitute those most constantly met. It is our inability to gauge their progress satisfactorily that is largely responsible for the uncertain prognosis in chronic nephritis. Second, many patients with chronic nephritis die of uremia before renal function has diminished to such a degree as to render renal insufficiency any more than a contributing factor. Often the phthalein excretion lies between 20 and 30 per cent, and the blood urea nitrogen at a level of from 40 to 50 mg. per hundred cubic centimeters of blood. It is probable that this state of affairs is a toxemia, but from what tissue this poison originates, what its nature is, and what the exact conditions are that call it into action are all open questions. The sudden rise of blood nitrogen seen in one of Dr. O'Hare's cases may possibly indicate an excessive protein destruction which I believe is characteristic of certain phases of the toxemia under discussion. Third, if all the above vicissitudes leave the subject of chronic nephritis alive he finally develops an increasing renal insufficiency to which he succumbs. This is a very prolonged process and it is almost incredible how low renal function may drop and the patient maintain at least fair health. Dr. O'Hare's report illustrates this very well. I have seen some similar cases though more of them were followed for as long a period. In another condition, polycystic kidney, in which an uncomplicated renal insufficiency develops, the same phenomenon of prolonged life with a maximal impairment of renal function is often found. As far as prognosis is concerned, it becomes evident that only very few nephritic patients really die as the result of renal insufficiency but that most of them cease to live because of extrarenal influences.

DR. EDWARD F. WELLS, Chicago: Satisfactory management of the patient depends largely on taking him into full confidence as to the diagnosis, the prognosis, and the general plan of treatment. Chronic interstitial nephritis is not a disease of the kidneys alone, but the blood vessels, heart, lymphatics, and other tissues are so essentially implicated that it is impossible to separate them. It takes a profound clinician to estimate within wide limits, the excretory capacity, under stress, of the interstitial nephritic kidney; and it requires a wiser physician than most of us to state how long any one of these patients may live. I have seen patients in whom the output of urea was extremely small for many successive months, in whom, when placed on some extra strain the kidneys have passed such quantities of urea as are beyond ordinary credence. Therefore, our prognosis should be extremely circumspect. Our first examination of a chronic interstitial nephritic patient should be made with painstaking care, and accuracy. The renal capacity should be estimated as closely as possible from several points of view, as, e. g., the excretion of water, of salt, the rapidity and completeness of the passage through the circulatory system, including the lymphatic circulation, of titratable solutions, and of the output of some of the waste products of metabolism. I value highly the measurement of the capacity of the kidneys to excrete urea, and always include this as an important feature of the investigation. The dietetic, regimental and medicinal measures which we employ may, probably, assist the kidney in its functions. However, some adventitious conditions are beyond our control as, e. g., the entrance into the system of an acute infection. In my own experience these most frequently transform, by disturbing the circulatory balance, a satisfactory progress to a condition from which the patient rarely completely recovers, and is often the beginning of a more or less prolonged downward course, ending fatally. Under these circumstances the patient will become dyspneic, and anemic; dependent edema will attract attention. It is absolutely necessary for the patient to maintain a posture as nearly horizontal as possible for a prolonged period, at least six weeks.

DR. LEWIS A. CONNER, New York: The second of Dr. O'Hare's cases illustrates a point which is of great practical

importance. That is, that in aged people the usual standards of normal kidney function are not applicable. If we attempt to prognosticate, in the case of people of 70 or 80 years of age, in terms of the standards of renal function which we apply to younger people, we are likely to make embarrassing mistakes. In such patients very low readings of the phthalein test and very high figures for blood nitrogen, creatinin, etc., are compatible with fairly good health and with many years of life.

DR. JAMES P. O'HARE, Boston: This type of case is a rare condition. We do not see it very often but we do see it often enough to warrant hesitancy in making a prognosis in a chronically sclerosed kidney. We have had also a few cases of the edematous chronic glomerular nephritis and the patients have lived for quite a considerable period, that is, for months, with a very low renal function, and then have died from a pneumonia. I was glad to hear Dr. Musenthal comment on the fact that death in the nephritic is very frequently due to causes not essentially nephritic but to other conditions like cardiac failure and infection. I have often been very much disappointed in cases that we had studied for a long time to find the patient dying of an acute infection or a cardiac complication when we were looking for a pure nephritis at necropsy. It is important for all of us to make records of our observations on these cases so that if a patient does live for a longer period than we expected, we can analyze the data obtained. Most of us do not do that. In fact, there has been no opportunity to do that until now because the renal tests were unknown until a few years ago. But now we have tests which are easy to make, and it is important to use them and make observations of these patients. Bear in mind, however, that even with our functional tests we are unable at present to make accurate prognoses. We make them with a fair degree of accuracy, but that degree of accuracy is often brought about by the fact that the patients die of an intercurrent infection or of cardiac failure rather than from the kidney disease.

THE TREATMENT OF CHEST INJURIES*

MARION A. BLANKENHORN, M.D.
CLEVELAND

The treatment of penetrating wounds of the chest early in the war was an unsatisfactory venture offering little prospects of development, but at the end was a very satisfactory procedure promising much in the improvement of its technic and the enlargement of its scope.

Methods of examination of a wounded chest are precise; and in contrast to the abdomen or head, the damage done by a foreign body can be estimated and the treatment indicated. Foreign bodies entering the chest usually continue moving in straight lines; they produce discoverable lesions and can be located accurately by the roentgen ray. With proper appliances and training, the surgeon can invade the thorax to make anatomic repairs and remove infecting foreign substances. The effect of various infecting organisms in chest wall, pleura and lungs is still the greatest unknown quantity of the problem and the one that has yielded the least to our efforts.

It is with little satisfaction that I review the statistical reports of the various surgeons in France and England, and with even less satisfaction that I inspect my own records during two summers in forward area hospitals and one winter at the base. There were no invariable concomitants—warfare and its wounds,

* Read before the Section on Practice of Medicine at the Seventy-ninth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1912.

hospitals, surgeons and surgeons' ideas changed with kaleidoscopic rapidity. It would be inaccurate history to collect and attempt to coordinate the case records made by the various surgeons in France and England, and futile to recommend anything for the future.

The generalizations dealing with the pathology of penetrating wounds of the chest, and the principles of treatment here given, constitute the lesson learned from various British and American surgeons in handling approximately 500 cases.

Chest wounds in patients coming to forward area hospitals can be divided into five main groups on a basis of their gravity and the urgency of their surgical treatment: (1) open pneumothorax, the so-called sucking wound; (2) extensive parietal wounds involving ribs and muscles; (3) large retained foreign bodies; (4) infected hemothorax, and (5) simple hemothorax.

OPEN PNEUMOTHORAX

It was apparent that there is no spontaneous cure for open pneumothorax. Anatomic repair is clearly indicated at once and is followed by almost miraculous, immediate relief. Patients who suck and blow a considerable volume of air through the wound were very uncomfortable, dyspneic and cyanotic, with a rapid, arrhythmic and irregular pulse of small volume. If untreated, they rapidly failed and died apparently from asphyxia. Simple stopping of the wound with a plug of gauze would revive a man in a few hours to the point at which he could undergo an extensive revision of his wound and closure. Patients who were so stopped up in advanced dressing stations arrived in good condition, frequently ready for immediate operation.

PARIETAL WOUNDS

Parietal wounds, penetrating or nonpenetrating, demanded the same consideration that wounds did anywhere else, with the additional reason that driven bone fragments became a source of infection. Broken ends of ribs projecting into the chest lacerate the lungs with each respiration, and occasionally do extensive damage to the heart and pericardium. Parietal wounds of less extent are a continuous source of infection to an adjacent hemothorax. A wound that connects with the pleural space by ever so small a sinus cannot be drained externally. As long as the aspirating effect of respirations is operating, the drainage is inward as well as outward. Such wounds, therefore, must be revised and completely closed. It was found preferable to convert a parietal wound into an open pneumothorax if necessary to make a thorough revision and a good closure.

Opening the chest freely has been found to be an easy and safe surgical procedure, well tolerated by a wounded man and causing very little shock. A very necessary part of the equipment needed to do surgery of the chest is a good nitrous oxid machine and a good anesthetist. When gas is given with a close fitting face mask and made to flow at considerable pressure, the lungs do not collapse when the chest is opened, and respirations and pulse are undisturbed. Furthermore, if anatomic repair of the chest wall and lung can be accomplished, the lung continues to function normally after operation.

RETAINED FOREIGN BODIES

Retained foreign bodies are dangerous as a source of infection and of mechanical erosion of large vessels.

Bullets and shrapnel balls that have not been deformed by impact with the soldier's equipment or bones, especially bullets, are surprisingly harmless. Shell fragments are invariably wrapped about with bits of clothing, and if they have one diameter as great as an inch, were almost never tolerated. To prevent empyema or lung abscess, they must be removed as soon as possible. Usually a man with a large retained foreign body is unfit for immediate operation on account of hemorrhage or shock or both. If considerable hemorrhage persists, he probably will never be fit to operate; resuscitation methods were unavailing, and it was not possible to operate for hemorrhage unless the hemorrhage was from a parietal vessel. Transfusion or infusion was distinctly detrimental if there was present a large hemothorax; for it could be clearly seen that the hemothorax was rapidly made larger, and the patients died suddenly with angina. The volume of fluid free in the chest apparently crowded the heart and lungs out of function.

Rest in a warm bed with plenty of fluids and morphin, usually restored these men to a condition that would tolerate an extensive operation. Removal of the foreign body was frequently an extensive operation. It required rib resection long enough to admit the hand into the chest. The fourth or fifth rib in the axillary space was best. The entire lung and chest could then be explored. The lung could be delivered down to the resection wound, and the foreign body with its pieces of clothing removed. If it was removed through healthy pleura, the pleura had to be sutured. If the foreign body was removed through a field of carnified lung, caused by the wound, it was usually unnecessary to make any closure or hemostasis, for this was quite well established by the process of carnification. How much should and can be done to carnified lung is a much disputed point. To me it was apparent that after gross contamination and necrotic tissue were removed, the less done the better. It was surprising how well such operations were tolerated, especially when done with gas given under pressure. Even the process of pulling on the lung caused very little change in blood pressure, pulse or respirations. After extensive lung injury and lung surgery, it was frequently impossible to maintain such a lung distended by the gas machine during operation or after closure; but gas pressure did prevent collapse of the sound lung during the operation, and prevented any disturbance of the heart and mediastinal vessels. Also it was not essential to a patient's well-being to have the wounded lung fully expanded after operation. In fact, it was thought by many that the lung should be kept collapsed and at rest after injury. But to accomplish this, collections of air or fluid in the pleural space was necessary, which introduced a new difficulty. One ingenious American surgeon accomplished partial collapse and rest by paralyzing the diaphragm with an injection of procain in the phrenic trunk, which was a rational and satisfactory procedure. Accumulations of blood were removed by pumping off the fluid and picking or wiping out all clot. The original wound of entry was revised, and when possible both wounds were closed tightly.

Infection of the pleural sinus was the greatest foe to the man who survived his anatomic injury. It was a surprise to all who observed it how able the pleural membranes are to combat infection. In all cases, whether operation was or was not performed, the

degree of contamination must have been very great, for gross dirt could be seen and removed; but these very chests could frequently be closed and occasionally remain closed with no other help than aspiration. Pleural membranes combat infection best when in their natural position and condition. For this reason, it is essential to prevent accumulations of air or fluid.

After operation and closure, serious exudates appeared which had to be tapped. Sometimes aspiration, two or three times repeated, finished the course of treatment. In others, the fluid continued to reaccumulate and finally became purulent; but by this time the lung had become adherent to the chest wall in its upper portions, and we then had a small empyema cavity localized at the base of the chest. Stitches were removed from the resection wound, and drainage was easily accomplished. Introducing air or antiseptic solutions into the pleura to keep the lung at rest puts the pleural membranes at a disadvantage, and infection is invariably more severe.

HEMOTHORAX

The remaining two groups, infected and uninfected hemothorax, were at first indistinguishable and were managed alike. The degree of contamination and the amount of free fluid are the principal determining factors. The bacteriology of these infections, like the bacteriology of other wounds, is unsatisfactory and incomplete, providing help for some cases but rules for none. Each case must be judged individually and then chiefly on clinical evidence, temperature and pulse being of the greatest help to determine when a hemothorax is infected and drainage is necessary. Streptococci and gas-forming organisms, when found in specimen fluids, invariably foretold or indicated drainage; but even these organisms were known to have disappeared from a pleural cavity after one or two tapings.

It was a practice in forward areas to hold all uncomplicated hemothorax cases when possible for observation, and after three days if there was only moderate fever and specimens showed no growth to evacuate the patient down to the base. It was observed that infections sometimes lay dormant for much longer periods than three days. Presumably the blood retarded the growth of organisms, or colonies were included in the clot and had to digest their way out into the fluid. The natural culture medium in such condition is the hemorrhagic fluid, and the resistance to infection is at the pleural membrane. It was best, therefore, to reduce the medium and increase the resistance relatively by tapping off fluid and keeping it tapped off. It was seldom that hemorrhage was lighted up by tapping, and it was quite certain that empyema was prevented and sometimes cured by tapping. Occasionally, clot interfered with tapping, and the convalescence of such an individual was much prolonged. Usually almost the entire volume could be drawn off as a fluid which would not clot. In every case in which I have seen operation performed, clot either of whole blood or of almost pure fibrin has been found, so that it is my opinion that clot forms in all cases, but that defibrination is accomplished occasionally by some means.

Many uninfected hemothorax patients made rapid and complete recovery without any interference whatsoever.

Infected hemothorax must as a rule be drained freely; but drainage which causes complete collapse

of a lung with the formation of a large cavity is very undesirable, for the collapsed lung frequently remains collapsed and the patient dies from a prolonged pyogenic infection of a large area of pleural membrane.

If free drainage can be delayed by repeated tapings until the partly expanded lung has established adhesions to the chest wall and only a small cavity is formed, the results are uniformly good. But there are certain cases, mostly when streptococci and gas-forming organisms are present, that become very septic and require drainage at once. Here a closed system of drainage by air-tight tubes and suction expands the lung, and provides the necessary adhesions to obliterate the empyema cavity. Irrigations of empyema cavities were generally practiced and found to be of considerable value—mostly to remove mechanically the accumulations of pus and clotted blood, and to diminish the number of organisms present.

Patients with free drainage usually did very well and could be evacuated to the base.

By the time patients arrived at the base in France, they had progressed to a stage that determined them either as having or not having empyema, provided medical lines of communication were normal. Frequently they were abnormal, and then all preconceived plans of management had to be revised, usually much to the detriment of patients.

For cases without drainage, the management at the base was much the same as in forward areas.

For cases with drainage, the management was much the same as practiced in civil surgery, except that in some cases empyema cavities were treated by the Carrel-Dakin method and closed very promptly, frequently with very good results.

I had little opportunity to see patients treated by this plan, for it was done chiefly by the French or in England.

ABSTRACT OF DISCUSSION

DR. ERNEST ZUEBLIN, Cincinnati: I am very much interested in Dr. Blankenhorn's paper, particularly from the standpoint of ordinary civil medicine. I would like to ask the doctor about the frequency of bilateral hemothorax, pneumothorax or hydrothorax. In a recent communication published in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, Captain Green makes the statement that contrary to leading conceptions the simultaneous tapping of both pleural cavities is attended by hardly any harmful consequences. Of course, this is very important, and I would like to know whether Dr. Blankenhorn's experience along this line confirms such a view. Also of practical interest would be the recommended irrigation of the pleural cavity in case of empyema. I am curious to know what solution military surgeons advocate, particularly if two cannulas are introduced, one above and one below, in order to provide for a proper elimination and a clearing up of the purulent fluid.

DR. MARION A. BLANKENHORN, Cleveland: In reply to Dr. Zueblin's question about double pneumothorax, I have seen quite a few cases of double pneumothorax, but, of course, not double open pneumothorax. Closed pneumothorax was almost always the rule in chest wounds. What I might say about double hemothorax would explain double pneumothorax. Bullets frequently traversed both chest cavities, producing double pneumothorax and large or smaller double hemothorax, and if infection did not follow, the results were quite good. As to irrigations: We were using irrigations principally for mechanical reasons, and we used the surgical solution of chlorinated soda mainly. This solution dissolves fibrin from the pleural membrane and dissolves fibrin away from the opening of the tube into the wound, and we thought

we were able to get rid of the original hemothorax more quickly by that process. Also, if organisms of putrefaction occurred, the odor was very promptly diminished, and we were also sure that the number of organisms was kept down. The plan of the management followed was to lay tubes along the walls of empyema cavities and give them routine irrigations, and when the bacterial count fell to a certain figure, close those cavities. I have not seen the statistics of those methods. Others have reported that if they did close in the presence of impending empyema, they would have to reopen, but if closure restored the normal condition to allow absorption of air and expansion of the lung, then they would have a smaller empyema. Frequently they would close and reopen a number of times. They considered this a much better method than to make no effort to expand the collapsed lung. The whole treatment was designed to obliterate the pleural sinus.

PERICARDITIS AS A COMPLICATION IN PNEUMONIA

BASED ON THREE HUNDRED NECROPSIES*

WILLARD J. STONE, M.D.
TOLEDO, OHIO

Records of 300 necropsies on pneumonia patients from the Medical Service of the U. S. Army base hospital at Fort Riley, Kan., are available for the purpose of this study. Among this number, pericarditis was found to have occurred in seventy-two, or 24 per cent. The types of pericarditis, as a complication in pneumonia encountered at necropsy, are shown in Table 1.

TABLE 1.—TYPES OF PERICARDITIS IN PNEUMONIA

	Number		Per Cent.
Acute serofibrinous pericarditis.....	14	19.4	
Acute purulent pericarditis.....	41	61.1	
Subacute fibrinoplastic and purulent pericarditis ("shaggy heart").....	14	19.4	
Total.....	72		

In addition, hydropericardium, without apparent inflammatory change, had occurred in twelve instances, or 4 per cent. Empyema was present in sixty-three of the seventy-two instances of pericarditis, or 87.5 per cent.

ACUTE SEROFIBRINOUS PERICARDITIS

In approximately 5 per cent. of the pneumonia patients on whom necropsy was performed, acute serofibrinous pericarditis had occurred. Among the fourteen instances, lobar pneumonia had occurred in eleven, and bilateral bronchopneumonia had occurred in three. This form of pericarditis was characterized by the presence of a flaky pericardial fluid, which was cloudy in appearance and which contained strings of fibrin adherent to the epicardium and pericardium. The quantity of fluid varied from 250 to 1,000 c.c.

ACUTE PURULENT PERICARDITIS

In approximately 15 per cent. of the pneumonia patients on whom necropsy was performed, acute purulent pericarditis had occurred. Among the forty-four instances, lobar pneumonia had occurred in thirty, bronchopneumonia had occurred in eleven, while a combined form of lobar and bronchopneumonia had occurred in three. The amount of pus in the peri-

cardium varied from 160 to 1,000 c.c.; the average in twenty-five instances in which the amount was recorded was 350 c.c.

SUBACUTE FIBRINOPLASTIC AND PURULENT PERICARDITIS

In approximately 5 per cent. of the pneumonia patients on whom necropsy was performed, the subacute form of pericarditis, characterized by a fibrinoplastic or villous and purulent exudate, had occurred, leading to the pathologic picture of the "shaggy heart" or cor villousum. Among the fourteen instances, lobar pneumonia had occurred in eight, and bronchopneumonia in six. The pericardium in all instances was lined by a partly organized villous exudate adherent to the epicardium. The amount of free purulent fluid usually associated with the fibrinoplastic exudate varied from 15 c.c. to 600 c.c., the average being about 250 c.c.

In Table 2 is shown the extent of the associated pneumonia incident to the three types of pericarditis.

TABLE 2.—PERICARDITIS AND THE EXTENT OF THE
ASSOCIATED PNEUMONIA

	No.	Both Lungs		Pneumonia— Right Lung		Left Lung	
		No.	Per Cent.	No.	Per Cent.	No.	Per Cent.
Acute serofibrinous pericarditis.....	14	7	50.0	4	28.6	3	21.4
Acute purulent pericarditis.....	44	21	47.7	9	20.4	14	31.8
Subacute fibrinoplastic and purulent pericarditis.....	14	5	35.7	6	35.7	4	28.6
Total.....	72	33	45.8	18	25.0	21	29.1

The importance of empyema as an associated complication in the pericarditis of pneumonia is shown in Table 3.

Acute purulent pericarditis.....	44	8	18.2	9	20.4	24	54.5
Subacute fibrinoplastic and purulent pericarditis.....	14	5	35.7	3	21.4	4	28.6
Total.....	72	17	23.6	17	23.6	29	40.3

TYPES OF INFECTION

A large proportion of the types of the pneumonia encountered were due to mixed infection by pneumococcus and streptococcus (usually one of the hemolytic varieties). When complications occurred in pneumonia, the predominating infection encountered was usually a hemolytic streptococcus; that is, 72.5 per cent. of 251 empyemas, in which the infection was known, were due to the streptococcus, while 27.5 per cent. were due to the pneumococcus. Such was the relative proportion also in pericarditis. In 75 per cent. of the cases, the cultures revealed hemolytic streptococci. In general, the type of infection corresponded to the type isolated from the pleural fluid.

COMMENT

In Table 2 it will be noticed that in seventy-two instances of pericarditis, both lungs were involved in the preceding or accompanying pneumonia in 45.8 per cent., while the left lung was involved in 29.1 per cent. and the right lung in 25 per cent. McHedran¹ has

* Read before the Section on Practice of Medicine at the Seventeenth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

1. McHedran, Alexander: Diseases of the Pericardium, in Osler: Modern Medicine, Philadelphia, Lea & Febiger 4: 41, 1908.

mentioned thirty-one cases of pericarditis from Osler's service at the Johns Hopkins Hospital, and has stated that both lungs had been affected in 41.9 per cent., the right lung in 41.9 per cent., and the left lung in 16.1 per cent. From these figures, and from the experience of himself and others, he concluded that pericarditis occurred more frequently in association with affections of the right lung than of the left. This has not proved to be the case in the series here reported, which showed in almost equal proportion for the two lungs.

The most important factor in the development of pericarditis appeared to be the occurrence of empyema. Reference to Table 3 discloses the fact that pericarditis, especially the acute purulent form, occurred more frequently with empyema of the left pleural cavity (54.5 per cent. with left empyema, and 20.4 per cent. with right empyema). For all three forms of pericarditis described, it will be seen that this complication occurred with left empyema in 40.3 per cent., and with right empyema in 23.6 per cent. Pericarditis occurred more frequently in association with left empyema than with lateral empyema. This may be explained by the fact that the development of empyema on the right side occurred, in a number of instances, as a late complication subsequent to the empyema on the left side. Pericarditis was one of the principal causes of death in empyema. Among forty-eight empyema patients who died subsequent to operation, extensive pericarditis, usually of the purulent form, was present in fifteen, or 31.2 per cent., while among 100 empyema patients who died without operation, pericarditis, usually of the purulent form, was present in 46 per cent.

DIAGNOSIS

In the diagnosis of pericarditis, the clinical sign of greatest importance was a to and fro friction sound, not transmitted beyond a limited area, which was usually first heard over the base of the heart or in the fourth or fifth interspace close to the sternum, and which was practically synchronous with the heart beat. It possessed a distinct rubbing quality, not unlike but less perceptible than a pleural friction sound. The remits of the rub could in some cases be detected by palpation. Its duration was transitory if effusion occurred rapidly, when the heart tones became distant or muffled, and obliteration of the cardiac impulse occurred. The differentiation of the pericardial friction sound from a pleural or pleuropericardial friction rub, in a patient with dyspnea due to pneumonia, empyema or a partially collapsed lung, was a matter of great difficulty in numerous instances. In some patients, the friction rub could best be heard below the angle of the left scapula, because of the transmission through a portion of consolidated lung. The heart was in some

instances distinctly rotated on its long axis toward the posterior chest wall, because of mediastinal adhesions arising from earlier mediastinitis. With effusion into the pericardium, the area of heart dullness increased to the right beyond the sternum, and to the anterior axillary line on the left. With marked effusion reaching 500 to 800 c.c., the area of dullness occupied a large portion of the left anterolateral chest wall. This area of dullness was often confusing if associated with the presence of fluid in the left pleural cavity. The roentgenogram was of great assistance in confirming the diagnosis of pericardial effusion in patients with increased area of heart dullness and with muffled heart tones, who also had walled-off fluid in the left lateral pleural cavity.

With marked distention of the pericardium, the veins of the neck distended, and in some instances a positive venous pulse in these vessels was evident, owing to the overfilled right auricle. At necropsy, dilatation of the right side of the heart was frequently mentioned in the necropsy notes. The myocardial changes, viewed

microscopically, consisted of cloudy swelling and fatty degeneration, with fragmentation of the muscle bundles.

Since pericarditis occurred, in our experience, only one-eighth as frequently in patients without empyema as in patients with empyema, the occurrence of a possible purulent pericarditis was suspected in every empyema patient who presented, after pleural aspiration or drainage operation, a rapid pulse and a septic type of temperature. Dyspnea was so common a symptom in patients with an extensive pathologic condition of the chest associated with empyema that, by itself, little reliance could be placed on it.

In the diagnosis of small amounts of purulent material in the pericardium, the clinical signs were in numerous instances untrustworthy, and the roentgenograms of little assistance. It was not at all uncommon to see at necropsy the normal amount of pericardial fluid replaced with thin fibrinopurulent fluid. If the process had existed a number of days, as judged by the clinical history, fibrin organization had taken place in some instances, with firm villous adhesions between pericardium and epicardium, producing the pathologic picture of the "shaggy heart." There was usually a small amount of unorganized, thin pus in the pericardial cavity. This form of pericarditis was undoubtedly such from the beginning. In the presence of an empyema the condition appeared to have resulted from an extension by contiguity to the pericardium. In only two of the forty-four instances of purulent pericarditis did empyema not exist as an associated or antecedent condition, and in one of these a fibrinoplastic pleuritis

Fig. 1.—Pericarditis following pneumonia. Three aspirations of serofibrinous fluid. Recovery.

was present, cultures from which revealed streptococcus infection.

The infection either reached the pericardium through the lymphatic vessels draining the parietal pleura, or

sion and drainage, because of the presence of the associated pulmonary and pleural pathology.

Pericarditis occurred as an early and as a late complication in pneumonia. As an early complication it was found at necropsy in patients who so quickly succumbed to a rapidly spreading pneumonia with empyema that the presence of pericarditis was unsuspected. As a late complication it occurred subsequent to operation for the relief of empyema. In not one instance among 275 operations for empyema was purulent pericarditis recognized, or believed to be coexistent with the empyema at the time of operation. It was many times suspected, but on evidence insufficient in the presence of pleural sepsis to warrant radical exploration of the pericardium. Subsequent events proved the wisdom of conservatism in the method adopted. In a strict sense, pericarditis developed, as did nephritis, subsequent to empyema and, as such, contributed largely as a cause of death in empyema, in many instances weeks after pleural drainage was established. If one might be so fortunate as to recognize purulent pericarditis coexistent with or subsequent to empyema, and the condition of the patient was such as to warrant further interference, free incision and drainage of the pericardium would be indicated. It has not fallen to my lot to be placed in such a position.

In performing paracentesis pericardii, local anesthesia of the skin and the deeper tissues was employed. Two points of election were available: A point outside the nipple, in the left fourth interspace, was the first selected. If the needle was inserted in an inward and backward direction toward the spine, keeping within the area of dullness and assisted by the roentgenogram shadow, there appeared to be little danger of puncturing the myocardium of the right ventricle, which occu-

Fig. 2.—Hemorrhagic pericardial effusion following tuberculous pneumonia.

extension occurred by contiguity of tissue from purulent accumulations beneath the sternum, which we have described as subcostosternal pus pockets, or from walled-off pockets occupying the left anterolateral portion of the chest cavity. In many of the patients with purulent pericarditis, the area of heart dullness was not increased by percussion, nor did the roentgenogram show cardiac enlargement, since distention of the pericardium had not taken place. There had merely been a change from a serous to a purulent fluid in the sac, with a subsequent partial organization of the exudate. The distant or muffled heart tones characteristic of considerably increased fluid in the pericardium could not be relied on for the diagnosis of the condition in such instances. A left-sided, closed pneumothorax, with collapse of the lung and retraction of the heart by adhesions toward the posterior chest wall, so muffled the heart tones in some patients as to lead to suspicion of pericardial effusion, when such a condition did not exist. A hemorrhagic pericardial fluid was obtained on aspiration in but one patient, who had undoubted tuberculosis with tuberculous pericarditis.

TREATMENT

Since a large proportion of the deaths in this series occurred in patients with an extensive pathologic condition of the chest due to empyema, it was impossible to consider any more radical procedure than paracentesis in dealing with pericardial effusion, whether serous or purulent. In the acute, purulent form, as well as in the subacute fibrinoplastic and purulent form in which, in many instances, distention of the pericardium had not taken place, little could be expected from paracentesis or, for that matter, from free inci-

Fig. 3.—Pericardial effusion and left encapsulated empyema. Operative Series II, No. 3. Recovery.

pled the greater portion of the heart surface proximal to the chest wall. The other point selected was immediately beneath the costal margin, in the narrow angle formed by it and the xiphoid cartilage on the left side. This point was available only if the diaphragm on the

left side was in normal position. In many patients with empyema, the diaphragm was higher than normal on the affected side. In inserting the needle for aspiration at this point, it should be inclined so as to hug the under surface of the costal cartilage, and be pointed slightly to the left toward the nipple until it enters the pericardium.

A fairly good sized needle for attachment to the aspirating syringe should be selected. For persons with thick chest walls, the needle should be about $3\frac{1}{2}$ inches long. When the point of the needle touched the myocardium, a distinct thrust, due to the cardiac systole, was evident.

In the treatment of pericarditis, the ice bag and morphin were used to control pain. Antistreptococcus serum, injected intravenously in from 50 to 100 c.c. daily doses, was used to combat the general sepsis in patients with streptococcus infection. Serums known to agglutinate, in dilutions of from 1:60 to 1:80, the strains of streptococci encountered, were used so far as possible. It is possible that recovery in some instances of empyema sepsis, with which suspected pericarditis was associated, was secured through its use.

SUMMARY

1. Pericarditis was found to have occurred in seventy-two, or 24 per cent., of 300 patients who succumbed to pneumonia.

2. Acute purulent pericarditis occurred in 61.1 per cent. of the seventy-two instances, acute serofibrinous pericarditis in 19.4 per cent., while the subacute fibrinoplastic and purulent form producing the "shaggy heart" occurred in 19.4 per cent.

3. The quantity of pericardial fluid present in acute serofibrinous pericarditis varied from 250 to 1,000 c.c. With this form, pneumonia of both lungs was present in 50 per cent. of the patients, of the right lung alone in 28.6 per cent., and of the left lung alone in 21.4 per cent.

4. In acute purulent pericarditis, the quantity of pus in the pericardium varied from 100 to 1,000 c.c. The average in twenty-six instances in which the amount was recorded was 350 c.c. Pneumonia involving both lungs had occurred in 47.7 per cent. of the cases, involving the left lung alone in 31.8 per cent., while in 20.4 per cent. the right lung was alone involved. In 54.5 per cent. of these instances, empyema of the left pleural cavity was present.

5. In the subacute form of fibrinoplastic and purulent pericarditis, producing the so-called "shaggy heart," pneumonia of both lungs had occurred in 35.7 per cent. of the cases, of the right lung in 35.7 per cent., and of the left lung in 28.6 per cent. Bilateral empyema had occurred in 35.7 per cent. of these instances, right empyema in 21.4 per cent., and left empyema in 28.6 per cent.

6. The type of infection isolated from the pericardial fluid corresponded generally to the type of infection isolated from the pleural fluid. In about 75 per cent. of the patients streptococcus infection (usually one of the hemolytic varieties) was present.

7. The most important factor in the development of pericarditis appeared to be the occurrence of empyema. Pericarditis appeared to have resulted by contiguous extension from an empyema in many instances. Pericarditis and the associated myocardial changes were important contributory causes of death in empyema, both prior to and subsequent to operation.

8. In the diagnosis of pericardial effusion in amounts varying from 300 to 500 c.c., the physical signs and the roentgenograms were fairly dependable, despite the extensive, associated pathologic condition which confused the picture. In the diagnosis of smaller amounts (from 10 to 150 c.c.) of purulent material in the pericardium, the clinical signs were untrustworthy and the roentgenograms of little assistance.

9. Paracentesis of the pericardium was an important diagnostic and prognostic procedure. In acute serofibrinous pericarditis with large effusion, aspiration of the fluid was an important means of securing relief for the cardiac embarrassment.

10. The more radical procedure of incision and drainage of the pericardium in purulent pericarditis was not considered advisable in any of these patients, in which the condition was suspected, because of the extensive, associated pathologic condition.

ABSTRACT OF DISCUSSION

DR. CHARLES SPENCER WILLIAMSON, Chicago: Just before the entrance of the United States into the war I was engaged in the experimental study of pericarditis and to this end injected gelatin agar mixtures into the pericardial cavity of thirty-three fresh cadavers, and then made casts from them. These casts were exhibited at the New York meeting of the American Medical Association in the scientific exhibit. To one of these cases I wish to refer since it was a unique opportunity. A patient with an upper lobe pneumonia developed a pericardial rub and shortly afterward we made the diagnosis of fluid being present. The following day, hearing that the patient was rapidly growing worse, I went to the hospital and found him with a very rapid, weak pulse and in a dying condition. Before we could make plans to aspirate the patient died. A few minutes after death I made a small incision in the costophrenic angle, inserted a long needle and aspirated 270 c.c. of turbid fluid containing pneumococci. I immediately injected exactly the same amount of gelatin agar solution and twenty-four hours later removed the pericardium en masse. This was frozen and a cast and model made. The size of the exudate as measured on the model was 405 c.c. The important point is that even with

this small exudate the great veins and the auricles were absolutely flattened. Practically we had a repetition of the animal experiments of Francois, Franck and Starling. The fluid had accumulated so rapidly that the pericardium did not distend sufficiently and in my judgment the patient died from the mechanical interference of the circulation due to pressure on the auricles. The important therapeutic indication is to remember that when an effusion is poured out rapidly the condition of the patient may suddenly become alarming and aspiration of even a very small quantity of fluid may be lifesaving. In other words, a small effusion accumulating rapidly may kill the patient where a large effusion accumulating slowly may be well borne.

DR. C. F. HOOVER, Cleveland: Paracentesis may be done for relief of infection of the pericardium or for relief from pressure within the pericardial sac. Whenever there is a question of performing paracentesis for the relief of pressure within the pericardial sac I am guided by the movements of the costal borders from the subcostal angle to the eighth rib. When the subcardial part of the diaphragm is flattened there will be inspiratory narrowing of the subcostal angle. If the subcardial portion of the diaphragm is not flattened then there will be no need of relieving the pericardial pressure. Another sign I have found very valuable in estimating the need of paracentesis of the pericardial sac is pallor of the lips. When the circulation is failing on account of pressure in the sac the lips are pale and the pulse small. Pallor of the lips is not caused by failing circulation when the myocardium is at fault. Distension of the pericardial sac causes greater hepatic displacement than any other intrathoracic disease. The liver is rotated downward on a transverse axis which is located at that part of the liver not covered with peritoneum. Seven hundred cubic centimeters of fluid in the sac was sufficient on one occasion to rotate the liver downward until the lower border was in the iliac fossa.

DR. WILLIAM H. ROBEY, JR., Boston: I have been very much interested in the remarks of the speakers, especially in what Dr. Hoover said, because I think that any light which can be thrown on the diagnosis of fibrinous, serous or purulent pericarditis is of great value. I have noted in the plates which Dr. Stone showed that the cardiohepatic angle was not obtuse. It is more often obtuse in large serous effusions than in small purulent ones. I do not think it is the opinion of observers that relatively large amounts of fluid in the pericardial sac produce signs of pressure. It is only when the fluid is first forming before the distensible pericardial sac has accommodated itself to the increased pressure or when the amount is very large that there are signs of discomfort. At the meeting last year Dr. Christian reported some interesting cases of posterior accumulations of fluid which caused signs of compression of the left lung within the angle of the scapula, known as "Ewing's sign." I recently saw in France a case with thirty-two ounces of pus in the sac and because the cardiac impulse was perfectly distinct the surgeons would not believe that the pus came from the pericardial sac even after operation. In another case with pericardial rub followed by increasing cardiac area, Ewing's sign was present. There was a dry tap and at the necropsy the pericardial surfaces were adherent. Ewing's sign failed in this instance. I notice that Dr. Stone and some others caution physicians not to puncture the heart wall in aspiration. I have often gone into the heart wall and have never seen it do any harm. In looking through the literature I have found only one case where the patient bled to death because the needle entered the ventricle. Indeed, in small amounts of fluid, the pericardial space being purely potential it is almost impossible not to strike the heart wall. One of my friends told me that he has given immediate relief to cases of marked cyanosis and dyspnea by aspirating the embarrassed heart and has never seen anything but good come from the operation.

DR. HENRY SEWELL, Denver: A pericardial effusion may affect the welfare of the individual in two ways, namely, through the quality of the fluid, its infectiveness, or through its amount. A non-infective effusion works its harm by preventing full diastolic distension of the heart. The restraint

thus offered depends on the relation of two factors, namely, volume of the fluid and capacity of the pericardial sac. The latter factor is itself variable but data on the conditions of pericardial distensibility seem to be wanting. It is conceivable that a pericardial effusion of moderate amount may cause sudden death by pressure on the great veins entering the right auricle while the patient lies on his back. In such a case the obstructive pressure might presumably be relieved by turning the patient on his face. Some of the speakers are to be congratulated on their immunity from harm in puncturing the heart itself during paracentesis. It seems to be a question of luck. I recall a case of cardiovascular disease in which the left pleural cavity was tapped by a well known surgeon for removal of serous exudate. The patient died in a few hours; the necropsy disclosed a pericardial sac distended with blood. The aspirating needle had cut into a superficial coronary vessel on the left ventricle and the patient bled to death into her pericardium. We all remember Kremecker's demonstration of the localized coordinating center in the middle of the anterior surface of the right ventricle, irritation of which, in the dog, produced fibrillation of the heart.

DR. WILLARD J. STONE, Toledo, Ohio: I have never seen displacement of the liver downward in extensive pericardial effusions because practically all of our cases, at least seven-eighths of them, were associated with empyema in which high fixation of the diaphragm had occurred on the affected side. Such high fixation would operate to prevent downward displacement of the liver if associated with rightsided empyema. In connection with the description which Dr. Robey mentioned of Dr. Christian's paper last year before this section, one of the plates this morning showed a distinct rotation of the heart toward the posterior chest wall. In that case the signs of effusion and dullness were very marked in the back. We have believed in such cases that an adhesive mediastino-pericarditis had occurred which had caused rotation of the heart toward the posterior chest wall accounting for the physical signs which were found in the back. These signs were accentuated if transmitted through a portion of contiguous consolidated lung. I do not believe that the sign described by Ewing is of any great significance in connection with pericarditis, except as it explains the associated chest pathology. I am sure, in doing paracentesis of the pericardium, that I have punctured the ventricle of the heart a number of times. I do not know that any particular harm has followed the incident, but believe, of course, that it is just as well to avoid puncturing the ventricle if it is possible to do so. To carry a needle through a thickened septic pericardial membrane, through the ventricle and into the blood stream is hardly a very desirable surgical procedure. If one uses the roentgenogram as a guide and keeps within the area of heart dullness, a point to the left, below and just outside the nipple, is on the whole the most satisfactory point for aspiration. The angle between the xiphoid and the left costal border was rarely available in our series because of the high diaphragm associated with empyema. I should like to ask Dr. Robey if he has ever seen any harm come from puncturing the ventricle in pericardial paracentesis.

DR. WILLIAM H. ROBEY, JR.: Not in my experience or in that of my friends, and I have found but one case in the literature where any harm seemed to have come from it.

Deaths from Disease and War in Great Britain.—The statement that the devastations produced by disease in times of peace are even greater than the loss of life from war may be illustrated by the experience of England and Wales. In the four years, 1911-1914, immediately preceding the world war, 2,036,466 persons died in England and Wales, while, according to official figures, the total loss of men during the four and one-fourth years of war was 835,743, including 161,800 presumed dead. The war figures give the entire loss for the British empire; but it cannot be far from the truth to state that war on the gigantic scale of the war from which we have just emerged has killed in Great Britain about one-third as many as have died in the civilian population in a corresponding period.

HYPERTROPHIC PULMONARY OSTEO- ARTHROPATHY (BAMBERGER- MARIE DISEASE)

REPORT OF A CASE FOLLOWING LUNG ABSCESS *

SEWARD ERDMAN, M.D.

Major, M. C., U. S. Army; Chief of the Surgical Service,
Base Hospital

WITH ROENTGENOGRAMS BY

WALTER A. OSTENDORF, M.D.

Captain, M. C., U. S. Army
FORT SAM HOUSTON, TEXAS

In the surgical service of the U. S. Army Base Hospital at Fort Sam Houston, Texas, I became deeply interested in a case of draining lung abscess associated with enormous enlargement of the hands and feet, with ossifying periostitis of certain long bones and with fluid in the knee joints, evidently a case of subacute infectious osteo-arthritis.

REPORT OF CASE

Clinical Picture.—March 20, 1919, I found a young man having the appearance of a chronic invalid, but he was not confined to bed. He was rather pale and slightly emaciated. His facial expression was listless and dejected. Speech and mentality were rather slow. He had a chronic cough which occurred in paroxysms with the production of moderate amounts of thick, tenacious, mucopurulent sputum, at times streaked with blood, with a musty but not offensive odor. Most striking was the enlargement of the hands and feet, the hands resembling huge, clumsy paws. The wrists were enlarged after the manner of the hands. The fingers were generally thickened and sausage-shaped, but were not "clubbed"; indeed, the greatest enlargement was over the proximal interphalangeal joint. The finger nails were large, square and flat, smooth and without any of the curving seen in "simple clubbed fingers"; the large nails were only in proportion with the huge fingers. The elbows were slightly enlarged. The feet and toes were correspondingly enlarged, and there was moderate edema of the legs, with pitting on pressure. The knees were markedly swollen and contained fluid. There was slight tenderness to pressure over the

History.—B. M. W., aged 24, first lieutenant, Flying Detachment Air Service, was admitted, Aug. 1, 1918, to the base hospital.

Family history: His father was alive, aged 54. He had had glycosuria for one year. His mother was alive and well, aged 43. All brothers and a sister were alive and well. There was no history of tuberculosis or cancer.

Personal history: The patient had had measles and mumps in infancy, and scarlatina at the age of 6. He gave a vague history of "rheumatism," saying that his feet had

Fig. 2.—Appearance of the feet of patient in November, 1918.

been swollen at times, but he was never confined to bed on this account. He had had occasional colds, but had never had tonsillitis until December, 1917. He had had no other illnesses. He stated that he had had no venereal disease.

Present illness: In December, 1917, while on duty with the Flying Corps, he "caught cold" and had tonsillitis. He was advised to have the tonsils removed.

Jan. 8, 1918, tonsillectomy was performed under ether anesthesia, in Philadelphia. He remained in the hospital only twenty-four hours. A few days later he developed a cough and pain in the left chest, at times referred to the left side of his abdomen.

February 1, he took to his bed and remained there for three weeks, suffering from what his physician called "pleurisy" of the left chest.

His cough persisted for about ten weeks.

March 19, he reported for duty at Kelly Field No. 2, Texas, and began flying. About this time his cough left him and he says that it did not return until after an accident in May in an aeroplane.

May 29, his aeroplane dropped from a height of 700 feet, but he was not seriously injured; he did not lose consciousness, but he was bruised and considerably shaken up. His chin was lacerated and his upper central incisor tooth was knocked out. This tooth was not found, and he wonders whether he may have "aspirated" it. There was no roentgenologic evidence that such was the case. No bones were fractured, and he remained in the hospital for only four days, reporting for duty on the sixth day after the accident.

His cough returned, and except for short remissions has persisted up to the present time. After his fall he was not again permitted to fly and was soon given a sick leave for a month.

About July 20, on his return from sick leave, he first noticed "swelling of his feet and toes"; his cough was troublesome, and he was sleepless and easily tired on exertion. The legs and feet felt heavy, weak and stiff as if they had been "jammed."

August 1, he entered the base hospital at Fort Sam Houston where he has remained up to the present time.

Fig. 1.—Condition of the hands.

affected bones and joints, but there was no redness. The bones of the skull and the face did not appear to be affected. From the surgical wound over the ninth rib in the posterior scapular line, there was slight purulent drainage, and examination revealed that the sinus communicated with a bronchus. In walking, the gait was clumsy and shuffling; the head was held slightly forward and the shoulders drooped, but no kyphosis nor scoliosis was detected.

* Owing to lack of space, this article is abbreviated in THE JOURNAL by the omission of certain paragraphs and illustrations. It will appear in full in the author's reprints.

About August 15, the hands began to enlarge rapidly, attaining their maximum size (so far) within a couple of weeks. The paroxysmal cough, especially on lying down at night, caused violent frontal headache and insomnia. The headaches lasted only for a few weeks, and there have been none during the past six months; but the sleeplessness has persisted and is still a distressing feature despite the use of sedatives.

Clinical Course.—During August, there were slight rises of temperature during the afternoon, the maximum being 100 F., but usually about 99.4. The pulse ran between 98 and 108. There was much cough, sleeplessness, nervous irritability and depression of spirits.

Weight on admission was 133 pounds, which was about normal.

The physical and the roentgenologic examinations pointed to an involvement of the left lower lobe of the lungs. The heart was normal. The systolic blood pressure was 114. The enlargement of the hands and feet was as described above. The epitrochlear nodes were enlarged. Otherwise the physical examination was not significant.

Blood Wassermann tests were negative, August 6 and 9, and September 6.

The sputum was negative for tuberculosis in approximately twenty examinations.

Repeated examinations of the urine disclosed no albumin, no sugar and no casts. The specific gravity averaged from 1.009 to 1.020.

Blood examination. Aug. 2, 1918, revealed red blood cells, 4,740,000; hemoglobin, 70 per cent. (?); leukocytes, 11,200; polymorphonuclears, 72; large mononuclears, 3; small mononuclears, 25. There was no poikilocytosis nor chromatophilia.

The feces were negative for parasites.

In September, 1918, efforts were made to locate pus which was suspected in the left chest, and several unsuccessful aspirations were made.

September 13, a small amount of thick pus was aspirated from the left

chest posteriorly at a depth which seemed to indicate a lung abscess, and at once costectomy of the eighth or ninth ribs in the posterior scapular line was performed and the parietal and the visceral pleura were sutured together, as the first stage of a two-stage operation for lung abscess. The operator was Major Russell.

September 17, through the costectomy wound, an abscess deep in the left lower lobe was opened with the cautery and a considerable amount of pus was evacuated and the abscess was drained.

From September, 1918, up to the present time, there has been more or less drainage of thick pus from the wound. Surgical solution of chlorinated soda (Dakin's solution) was not well borne on account of the communication with the bronchus.

At one time in February, 1919, the discharge gradually ceased and the wound closed but opened again spontaneously about sixteen days later, and discharged a bit of greenish, gangrenous tissue.

At the present time, there is still slight purulent drainage

and free communication with the bronchus, namely, a chronic bronchial fistula.

During these months whenever the drainage seemed insufficient there occurred an exacerbation of the cough, mental depression and above all an increase in the size and in the aching pains along the enlarged bones and joints of the extremities, but without local heat or redness.

In January, 1919, the knees became more swollen and filled with fluid.

The treatment during this time has been surgical care of the wound in the chest, symptomatic treatment for the pains and the insomnia, and during December, 1918, the injection of an autogenous vaccine prepared from the pus.

This vaccine contained *Staphylococcus albus*, and a gram-negative typhoid-like bacillus. No effect was noted from its use.

The sputum, March 4, 1919, was thick, mucopurulent, and streaked with blood. Culture shows *Micrococcus catarrhalis* and a green-producing nonhemolytic streptococcus. There was no elastic lung tissue. The odor was musty but not very offensive.

Blood examination. March 2, revealed: red blood cells, 5,740,000; hemoglobin, 80 per cent. (?); leukocytes, 11,400; polymorphonuclears, 54; small mononuclears, 39; large mononuclears, 4, and transitionals, 3.

The systolic blood pressure was 110; the diastolic, 64.

Fluid from the left knee was aspirated, March 6. Smear and culture were negative.

Ear and throat examinations were negative.

Eye examination. March 11, 1919, revealed: vision right eye 20/20, left eye, 20/20. The media were clear. The fundi were normal. The field of vision for form was normal in extent in both eyes.

The weight was 133 pounds Aug. 1, 1918, and 122 pounds, March 15, 1919, a net loss of 11 pounds.

The height was 64 inches, June, 1917, and 64½ inches, March 18, 1919.

The thyroid gland appeared to be normal.

There has been practically a normal temperature for months with occasional elevations to 100 F. at times when the drainage has been temporarily blocked.

The pulse still averages from 96 to 104.

Summary.—There was an involvement of the left lung, probably the effect of an aspiration infection following tonsillectomy under ether. There was a chronic productive cough. There was a rapid enlargement of the feet and hands during a period of six months. A lung abscess was drained, September, 1918, with a resulting persistent, bronchial fistula. Mental depression and insomnia were present. There was a slight loss of weight. There was no evidence of syphilis or tuberculosis. The pathologic condition in the enlarged hands and feet and other regions is best revealed by the roentgenograms which show, besides the enlargement of the overlying soft parts, a definite striated production of new bone in the periosteum of the shafts of the metacarpals and the first two rows of the phalanges, also along the lower ends of the radius and ulna. The

Fig. 3.—Condition of patient, March 20, 1919.

Fig. 4.—Appearance of hands and legs, March 20, 1919.

corresponding bones of the lower end of the femur; also the clavicles and some of the ribs, are to a degree affected. The joint surfaces appear unaffected. There is fluid in the knee joints.

Negative Findings.—The fingers are not "clubbed." No pituitary or thyroid changes are present. There are no

periosteal changes in the long bones, but we do not see the reverse.

In our case we cannot accept the last clause of Sternberg's statement, for we have a case with pronounced changes in the long bones and yet without "clubbing of the fingers," the fingers being very generally enlarged throughout and the nails, while proportionally large, not curved more than normal.

ETIOLOGY

The French writers were the first to attribute the origin of this rare disease to the absorption of toxins from a septic focus, usually in the lungs. This is the explanation now generally accepted; and in order of frequency the following foci have been encountered: bronchiectasis, empyema, abscess of the lung, pulmonary tuberculosis with cavity formation, toxic cirrhosis of the liver, and malignant tumors of the lung.

Sternberg mentions such other causes as pyelonephritis, dysentery, pneumonia, pleurisy, influenza, alcoholism and congenital heart disease; but Osler remarks that Sternberg must have included many doubtful cases. The tuberculosis theory is upheld by Poncet, Thorburn, Ball and Alamartine. Syphilis has also been advocated by certain French writers as the cause.

Fig. 5.—Thickening of the periosteum with irregular deposit of subperiosteal bone on metacarpals; also on proximal and middle phalanges (February, 1919).

headaches, disturbance of vision nor drowsiness; on the contrary, very marked insomnia. There are no changes in face, lips or skull. There is no evidence of abnormal thirst or hunger, and there are no alterations in the special senses.

HYPERTROPHIC PULMONARY OSTEO-ARTHIROPATHY

In 1890, Marie first reported a case which he described as "osteo-arthropathie hypertrophique pneumique," a distinct clinical entity, and yet, according to Babcock, this very case turned out later to be a case of acromegaly.

I have been unable to make a complete review of the literature, stationed as I am on military duty, but all the available authorities have been consulted and many and great are the discrepancies encountered.

From many of the articles it would appear that the writer never had seen a genuine case of this rare disease and had been obliged to draw on and still further confuse the already confused descriptions of preceding authors.

It is doubtful whether the whole literature up to the present time contains records of 100 cases; it is certainly the only case of its kind which has ever come under my observation.

One is struck by the emphasis laid on the clubbing of the fingers, which is not present in our case. We agree very heartily with Sternberg when he says that "one must suspect that many cases, so-called, are not all the same, and it is a question whether or not 'clubbed fingers' and the periosteal changes are related." Sternberg says that we see clubbed fingers without

Fig. 6.—Subperiosteal bone deposits on lower ends of tibia and fibula; posterior aspect of os calcis; anterior surface of astragalus and of metatarsals (March, 1919).

Cyanosis, if it were constantly present, might be called on to explain simple clubbed fingers, but it fails utterly to account for the bone changes.

The bone and joint involvement in our case indicate conclusively that the process is a subacute infectious

osteo-arthritis, and in our case, as in the vast majority of genuine cases reported, the focus of infection is in the lungs.

PATHOLOGY

In 1906, Alexander collected seventy-seven instances from the literature which he regarded as genuine cases of this disease, and he reviews the pathology of all the cases in which complete necropsies were performed (sixteen cases).

We quote Alexander's findings almost verbatim from Osler, and the description fits our case very perfectly:

Symmetrical deposits of new subperiosteal bone on the shafts of the long bones. Most frequently affected are the lower ends of the radius and ulna, the metacarpals and the first two rows of the phalanges; more rarely the lower end of the humerus and the upper ends of the radius and ulna. The new bone begins abruptly from 4 to 5 inches above the wrist joint and forms a sheath covering the lower ends as far as the epiphyseal line. The circumference of the bone is about equally affected, the thickest deposit being at the junction of the shaft with the lower extremity of the bone. The carpal bones are not affected, but the metacarpals are ensheathed and appear uniformly enlarged. The first two rows of the phalanges are similarly affected but less than the metacarpals. The terminal phalanges are apparently unaffected.

Fig. 9.—A sheath of new bone may be seen surrounding the shafts of the tibia and fibula. The cortex and medullary canal are apparently normal (March, 1919).

Similar bones of the lower extremity are affected, especially the lower tibia, which may be thickened by a layer of new bone one quarter of an inch thick. The phalanges of the toes are less affected than those of the fingers.

Deposits have been found on the iliac crests, on the clavicles and on the anterior surface of the patellae.

The symmetrical distribution is truly remarkable.

The cortex of the bone may show sclerosis and thickening, with diminution in the size of the medullary canal. The periosteum is very vascular and thick, and the main nutrient canals are large and many additional vessels enter the compact layer.

The bone changes are due to a chronic inflammation, causing new bone formation, also to atrophy and rarefaction and, to a much less degree, to osteophyte building.

The long bones do not bend. The skull is little, if any, affected.

In many cases there is excess of fluid in the joints, wrists, ankles, knees and fingers. In these affected joints the synovial membrane shows inflammatory changes, but there are no cartilaginous changes or flapping, no eburnation nor osteophyte building.

The bone changes are only part of the process, for there is much thickening of connective tissue, especially in the vicinity of the wrists, ankles and fingers.

Barker describes the affair as a slowly ossifying periostitis and osteitis, but he states that the joints are free.

Buck³ says that there is "an outside layer of dense, newly formed periosteal bone all along the shaft; this layer is striated and does not completely obscure the old cortical line. In pronounced cases all the bones in the body may be involved; the flat bones are thickened and there is marked kyphosis."

Fraenkel adds that it is "a true hypertrophy in consequence of periostitis, with new bone formation and at the same time a rarefaction of osseous tissue with dilatation of the natural interstices as well as increase of the medullary substance."

I make no attempt to harmonize the little discrepancies in the descriptions quoted above.

The thyroid and the pituitary glands are not altered.

TREATMENT

The treatment for the pains in the bones and joints is symptomatic. The only treatment which will logically have any effect on the progress of this race disease must be directed toward the cure or improvement of the primary focus in the lungs.

CONCLUSIONS

The history, the clinical findings and the roentgenologic findings in our case all point quite conclusively to the diagnosis of hypertrophic pulmonary osteoarthropathy, by which we mean a subacute infectious osteo-arthritis, secondary to a septic focus in the lungs. However, we must acknowledge that the roentgenogram of the skull shows an abnormally small sella turcica, and the possibility of some change in the pituitary must be admitted.

Is it possible that our case, like the first case reported by Marie, may later develop into an irregular type of acromegaly?

CONGENITAL BILATERAL STRICTURE OF THE URETER*

ISIDOR MUFSON, M.D.

NEW YORK

If we may judge from the literature on the subject, congenital stricture of the ureter is not rare; but a *bilateral* congenital stricture of the ureter is a rare defect, only eight cases, exclusive of the one here recorded, having been described. From the few cases recorded it would appear that these strictures are most often discovered at the extremes of life, most of them having become evident before the age of 5 years. Two cases have occurred in adults, one at the age of 25 years and the other at the age of 62.

No apparent reason for this congenital anomaly presents itself in studying the development of the urinary system. The ureters are primary derivatives of the bladder, growing cephalad to meet the metanephric tissue. Their lumina appear either as a result of central absorption of the epithelial outgrowth or are present primarily in the process of their evagination from the bladder¹. The failure of these processes to be completed would give rise to the obliteration of the lumen. Another explanation rests on an anatomic characteristic of the ureter in the embryo, namely, the presence of valves. In the case reported by Watson and Cun-

1. Huntington: *Harvey Lectures*, New York, 1906-1907, p. 222.

ningham,² it is probable that the valves became adherent at their margins or lost their elasticity and so caused the narrowing of the lumen.

In the ureter there are three sites of predilection where the lumen may be obliterated: at the junction of the ureter with the renal pelvis, at the brim of the bony pelvis, and at the vesical end. When the obstruction occurs at the vesical end, obliteration may occur just outside the bladder, or in the muscular coat, or at the bladder opening of the ureter. With obstruction just outside the bladder, there is a cystic dilatation extending up a variable distance from the bladder while the inner surface of the viscus is negative. With the stricture in the middle coat, there is no obvious abnormality, except perhaps a dimpling or a moderate pouting at the site of the ureteral opening. When the obliteration occurs at the ureteral orifice, there is a cystic outpouching from the ureteral opening which may vary daily in size, as in Buerger's case,³ or enlarge so that it may present at the external urethral meatus as in the cases described by Bostrom.⁴

As is to be expected, the narrowing of the lumen produces a back pressure which results in structural and physiologic changes in the tract behind the stricture. The extent of these changes is dependent on the degree of the atresia. If obstruction is incomplete, there is a dilatation of the lumen of the ureter accompanied by a hypertrophy of the wall. The renal pelvis becomes dilated, and atrophy of the pyramids and renal parenchyma follows. If the atresia is complete, the result is either an atrophy of disuse or a hydronephrosis, with or without a pyogenic infection. The fluid in the hydronephrotic cases, as Sollmann, Williams and Briggs⁵ have shown, possesses the characteristics of a transudate and not that of urine.

The cases occurring in the literature are, briefly abstracted, as follows:

REPORT OF CASES

CASE 1.—A man, aged 25, was operated on at the age of 14 for a right-sided hydronephrosis and at the age of 25 for a left-sided pyonephrosis (Wipple⁶).

CASE 2.—A bilateral congenital atresia occurred in an 8 month old fetus at the vesical opening of the ureters with beginning double hydronephrosis (Welz⁷).

CASE 3.—The age of the patient is unknown, but he presented a marked degree of bilateral hydronephrosis due to unyielding ureteral valves (Watson and Cunningham⁸).

CASE 4.—A boy who died thirty hours after birth presented a right ureter obliterated 5 cm. from the kidney and the left ureter obliterated 2 cm. above the bladder (Mutach⁹).

CASE 5.—A man, aged 62, presented a bilateral stricture at the vesical openings indicated by minute depressions at the tip of protrusions appearing at the normal ureteral openings in the bladder. This was probably the type in which the stricture was situated in the ureter as it passed through the muscular coat of the bladder (Burchard¹⁰).

CASE 6.—A boy who died one hour after birth from respiratory difficulties presented the ureter patent on the right side for a distance of 3 cm. from the bladder, the left ureter being patent for 2 cm. This author states that similar cases have been reported by Hoenes and Ahlfeld (Dyckerhoff¹⁰).

AUTHOR'S CASE

A boy, aged 1 month, was brought to the hospital with the statement that he had been restless and vomiting since birth. Birth had been normal. Physical examination revealed a marked state of malnutrition. The abdomen was much distended, the superficial veins being prominent on both sides. The child was moderately jaundiced. The temperature varied from 99 to 100 F. After three days in the hospital the infant died.

At the necropsy, aside from the jaundice of the skin and organs, only two abnormalities were found: the first of these was that of the gallbladder. The viscus was distended with a colorless mucoid substance, and the cystic duct was completely angulated on itself so that the two limbs were parallel. They were held in this position by a vascular band containing the cystic artery. On cutting this band the obstruction was released and the contents of the gallbladder could be expressed into the duodenum.

The second abnormality was in the urinary system: Both kidneys were enlarged, the pelvis and calices were dilated.

Congenital bilateral stenosis of ureter followed by hydronephrosis. Dilatation of calices, abscess pockets in kidney and diameter of ureter, as shown in cross section at lower pole of one kidney, should be noted.

and the pyramids were flattened. The left kidney presented several abscess pockets, the largest of which was 5 cm. in diameter. Both ureters were markedly dilated, measuring almost 1 cm. in diameter, the ureteral walls being 0.25 cm. thick. A probe could be passed through their entire course except at the vesical end where they permitted the passage of only a horsehair. The urethra was patent and the bladder showed no abnormality. The accompanying illustration shows the condition better than words can describe it.

Institution to Promote Cleanliness and Hygiene Among Schoolchildren.—The women of the Comité femenino de Higiene Popular of Spain have fitted up a building at Madrid equipped with all that is necessary for baths, etc., for schoolchildren, especially to "hygienize" the children as they are to be sent out of town to the seashore sanatoriums, school colonies and for other outings. The building has been placed at the disposal of the city authorities, and the work of caring for the children is done by the women of the league or the public health personnel. The children have their hair cut, the head disinfected, the mouth put in order and the teeth attended to by a woman dentist. There are douches and other bathing facilities and the institution is open for work every week-day, from 8 a. m. to 8 p. m., everything gratuitous. It is hoped to install more of these Casas de Higiene Benéfica Infantil in other crowded parts of the city.

ANKYLOSIS OF THE JAW DUE TO FIXATION OF THE TEMPO- RAL MUSCLE

METHOD OF TREATMENT*

GORDON B. NEW, M.D.
ROCHESTER, MINN.

It is sometimes difficult to determine definitely the side involved and the location of the fixation of an ankylosis of the jaw. This is particularly true in cases in which the jaws are fully formed before the ankylosis has occurred and in which there is no deformity. The diagnosis of the location is not so difficult when the fixation has occurred early in life, causing the deformity typical of such cases.

Ankylosis of the jaw may be said to be of three types: (1) articular ankylosis, the most common type, due to the involvement of the temporomaxillary joint,

Fig. 1. The superficial temporal artery, internal maxillary artery, facial nerve and the location of the incision.

(2) extra-articular ankylosis, in which the extra-articular structures or muscles are the cause, and (3) articular-extra-articular ankylosis, in which both the joint and the extra-articular structures are at fault. The clinical points of value in determining the side involved and the location of the ankylosis have been brought out in a recent article.¹

The treatment of the articular type of ankylosis gives uniformly good results. It consists of an arthroplasty of the temporomaxillary joint through a curved incision 2 inches long, extending above the zygoma and down in front of the ear, and the removal of at least one-half inch of the condyle and the ascending ramus of the jaw. It is not necessary to interpose any tissue in the new joint. When the jaw is not deformed, the operation is not difficult. If the typical deformity of ankylosis developed early in life is present, the joint

will be very low and should be attacked from above by removing the lower margin of the zygoma. In this way the facial nerve is avoided, which is liable to

Fig. 2.—Appearance after removal of a portion of the zygoma and exposure of the coronoid process, and the attachment of the temporal muscle.

injury if care is not taken in making the dissection in the soft tissues.

The treatment of the extra-articular and the articular-extra-articular types of ankylosis are much more difficult and present many problems. A recent

Fig. 3.—Appearance after removal of the coronoid process along with the attachment of the temporal muscle.

case of extra-articular ankylosis of the jaw, due to fixation of the temporal muscle, suggested a method of treatment which, so far as I know, is new for this type of case.

REPORT OF CASE

History.—N. A. B. (Case 118426), a farmer, aged 36, came to the clinic, Jan. 8, 1919, on account of inability to open his mouth. This trouble followed a gasserian ganglion operation here three and one-half years ago. The operation had been done by Dr. E. H. Beckman for trifacial neuralgia of several years' standing. The notes of the operation, July 21, 1915, follow:

"The operation was done in two stages. The Cushing incision was made, and large tortuous vessels were found throughout the entire dura. Because of the severe hemorrhage it was thought best to divide the operation into two stages and a gauze pack was inserted to be left in place for twenty-four hours. July 29, 1915, the second stage operation was done. The posterior root was evulsed and most of the ganglion removed. The bottom of the pocket was packed with gauze to control hemorrhage; the gauze was removed twenty-four hours later."

The patient made an uneventful recovery except that he was unable to open his mouth after the operation; he secured complete and permanent relief from pain.

The ankylosis was complete and the patient had received no treatment for it. Except for the scar in the left temporal region extending down in front of the ear, the face was symmetrical and there was no atrophy. It was believed that

could open his mouth, and in a week's time he was able to separate his teeth 1 inch. The facial nerve was not injured. He was given a screw-top mouth-gag, but he preferred to use wooden tongue depressors placed together on the flat to exercise his jaws; he could put nine of these between his teeth. He was able to chew meat or any type of food. This good function of the jaw has been maintained now for four months.

AN ORIGINAL TEST FOR THE PATHOLOGIC GREAT TOE SIGN

WITH ILLUSTRATIVE CASES *

LEO M. CRAFTS, B.L., M.D.

MINNEAPOLIS

While making a study of a remarkable grouping and diffusion of various reflex responses found in the following case of back injury referred by Dr. J. F. Norman of Crookston, in May, 1917, my attention was attracted by one among other highly interesting phenomena, to a sharp dorsal extension of the great toe occurring when an upward stroke was made with a blunt point over the anterior surface of the ankle. Application of this test in various cases following this observation led to the definite conclusion that an original method of eliciting the pathologic toe sign had been discovered.¹

REPORT OF CASE

CASE 1.—T., a single man, aged 52, while reaching under a section of barn floor which was being lifted by several men, was doubled over sharply when they accidentally let it down on his shoulders. He felt

Fig. 4 (Case 118426).—Complete ankylosis of the jaw due to fixation of the temporal muscle following gasserian ganglion operation.

Fig. 5.—Appearance after removal of the coronoid process and the attachment of the temporal muscle.

the ankylosis was due to the fixation of the temporal muscle either from cutting it across at the time of the operation or from secondary inflammatory reaction. The patient was given ether, and an unsuccessful attempt was made to stretch the jaws open. In order to restore the function of the jaw, an operation was performed.

Operation and Result.—The incision was the same as that used in the operation for arthroplasty of the temporomaxillary joint (Fig. 1). The skin and superficial tissues were incised down to the temporal fascia. A mastoid retractor was inserted and the zygoma exposed well forward. In elevating the soft tissues over the zygoma it is essential to keep close to the bone, thus preventing injury to the facial nerve. By means of blunt dissecting scissors and a periosteal elevator the inner surface of the zygoma was freed so that a piece of it 1 inch long was removed with a Gigli saw (Fig. 2). This piece was placed in a warm, wet gauze sponge. The temporal muscle and coronoid process were then exposed and removed with a curved chisel and a bone-biting forceps. The attachment of the temporal muscle to the inner surface and notch of the ascending ramus was removed by blunt, dissecting scissors (Fig. 3). The temporomaxillary joint was exposed but not opened, and was found to be normal. The piece of the zygoma that had been removed was replaced and sutured by catgut sutures, and the wound closed with catgut and dermal sutures. The following day the patient

a band of numbness around the midbody immediately, but continued his work. For three months he suffered from a dull pain in the region of the original numbness. This gradually improved, and was followed by sharp "cramplike" pains in the same zone. These subsided slowly and were succeeded by numbness in the feet, gradually rising to the waist line. About three weeks later the legs began to grow weak, complete loss of motion rapidly supervening, followed immediately by retention of urine.

The patient came under observation about four days following the onset of these symptoms. His general nutrition was poor, and he had lost 30 pounds. The face muscles and upper extremities were normal, but there was marked atrophy in the legs. The patellar response was abolished on both sides. There was no ankle clonus, but a marked Babinski response in each foot, and after an interval of about a second extension of the other great toe, accompanied by contraction of the adductors of the thigh. There was also positive reaction to the Oppenheim and Chaddock tests in both feet. Moderate dulling of tactile and pain sense was found over both lower extremities up to a point 2 inches below the

* Read before the Section on Nervous and Mental Disease at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

1. Preliminary material on the subject was presented before the Minnesota Neurological Society, Jan. 15, 1918, and an abstract published in *Minnesota Medicine* 11: 110 (March) 1918.

umbilicus, and of tactile sense only to a line 2 inches above this point. When the pin point passed the lower of these lines, in determining its topography, it was noticed that dorsal extension of the great toe occurred, accompanied by retraction of the leg. All motor power was abolished in both legs. The abdominal reflexes were obliterated. During the investigation of these various phenomena it was accidentally noticed that stimulation of the anterior surface of the ankle was uniformly followed by dorsal extension of the great toe. And various tests showed that the best response was produced by an upward stroke with a dull point, for a distance of about 2 inches.

A laminectomy was performed by Dr. H. B. Sweetser, May 5. The ninth to the twelfth spines were removed, exposing a brownish, fusiform, extradural mass opposite the ninth and tenth vertebral bodies. This was carefully removed and found to be a hypernephroma.

May 10, the patient reported his legs feeling more comfortable. The Oppenheim and the Chaddock responses had disappeared. The Babinski reflex was present on both sides; and an upward stroke over the ankle surface also produced extension of the great toe. Sensation had improved in the segmental zone below the

umbilicus, and that just above it had become hyperesthetic. May 28, it was reported that the zone of hyperesthesia had disappeared about two weeks before. Sensation was normal now to the line 2 inches below the umbilicus; but below this point there was no change. As the pin passed this line there was still an occasional extension of the great toe. The Babinski reflex was present on both sides, and muscular contraction of the shoulder and of the upper arm of the same side followed the test after about one second's delay; but diffusion did not now cause extension of the opposite great toe. Stimulation of the skin over each ankle also produced extension of the toe, and there was a slight Oppenheim on the right. Patellar response was absent, and no ankle clonus existed. There was no control of the bladder and no power in the legs. The patient returned to his home at this time.

About eight months later he reported continued improvement, with power to reflex and extend the legs, move the toes and to lift either foot from the floor. And he was then able to get from his bed to his wheel-chair and back alone.

COMMENT

All the various methods that have been devised by different observers for eliciting the great toe reflex, Babinski, Oppenheim, Gordon, Chaddock and that which I have described, are of identical significance, predicated definite involvement of the motor neuron at some level. The explanation of the occurrence of a positive reaction to one of these tests and its absence to others, in any given case, is an interesting study, and the reason evidently depends on the exact level of arc, or on the individual sets of fibers involved, one sensory stimulus linking with and another missing the activation of the exact motor path concerned. In properly bringing out the various responses, the skill of the technic employed is of distinct importance. All require deft application for accuracy and certainty of conclusion. To develop the Babinski response, Barker directs stroking with a blunt point along the inner plantar border. This is certainly not the best practice. The surest reaction is always found by stroking nearer the outer margin or across the ball of the foot. Sometimes it will be found only by stroking back near the heel; again, midway forward, and in many, only by a stroke

across the ball of the foot inward. At times a very light touch, at others deep and firm pressure, produces the best response. A quick stroke may be most effective in one instance, a slow movement in another. All should be employed to re-exact and complete knowledge. The clumsy rubbing of the thumb nail along the sole of the foot is extremely crude. A blunt-pointed instrument properly shaped for the purpose should always be employed for the Babinski test and for mine. Oppenheim's sign is best determined by running the soft ball of the thumb or finger tips, with firm pressure, down the lower 3 inches of the inner posterior border of the tibia. A similar movement around the external malleolus from behind forward brings out the Chaddock. And a quick, deep grasp of the calf muscles develops Gordon's sign. The best method for eliciting the reflex response under present consideration is by stroking with a blunt point upward over the dorsal surface of the ankle, for a distance of about 2 inches, the lower leg being horizontal and the musculature relaxed (Fig. 1). The amount of pressure necessary varies in different cases. A direct, quick thrust against the surface with the point of the instrument is sometimes effective, and a downward stroke occasionally also, but not as uniformly as the upward movement. Usually the test finds the best response when applied up the median line (Fig. 2), but occasionally it will be found either toward the inner or the outer side of the ankle surface.

Of all methods of developing the positive toe sign, Babinski's is undoubtedly most constantly effective. Of the others, I have found my method next in constancy, and distinctly more frequent than that of Oppenheim, while a response to either the Chaddock or the Gordon test is decidedly uncommon in my experience. To be clearly positive, a dorsal extension of the great toe is essential. Simple immobility of the toe is atypical, but its meaning or importance is not certain. The behavior of the other toes varies widely. They may flex, extend or remain inert; or they may spread, fanlike. This behavior of the small toes should have more careful observation for possible added value in the complete interpretation of these tests.

Fig. 2.—Typical dorsal extension of great toe in the application of the test.

While a considerable series of cases has been under observation and study in determining the value of this test, it is not deemed necessary or desirable to extend the text by detailing numerous case histories. Brief presentation, however, of one or two striking illustrations of its presence in chronic degenerative and acute inflammatory conditions may not be amiss.

ILLUSTRATIVE CASES

CASE 2—H. K., a man, aged 40, referred by Dr. C. M. Kistler, had had a chancre fifteen years before. He was a plumber by occupation, had been married twelve years, and of his seven children four were stillborn. He had pain between the shoulders and down the back for two years, and increasing trouble in controlling the urine. There had been a loss of sexual power in the preceding two months, and steadily increasing difficulty in walking; but he was in good nutrition and color. The right pupil was larger than the left and not circular; it did not respond to light. The iris had

that tense, flat appearance with loss of the normal velvety softness, as characteristic of the tubercle eye as the so-called Argyll Robertson pupil, which I first described² in 1917. There was moderate incoordination in the arms, and all arm reflexes were abolished. Patellar responses were entirely wanting. There was decided incertitude of gait and marked ataxia of station. No ankle clonus appeared, but marked Babinski. Oppenheim, Chaddock and Gordon reflexes were present, and a positive response to a stroke over the dorsal surface of the ankle on both sides. Serologic findings in the spinal fluid were positive; in the blood, negative.

Case 3.—Paul, P., aged 7, seen in consultation with Dr. G. M. Doran, Feb. 22, 1919, presented an unusual picture of acute bulbar paralysis (lethargic encephalitis), apparently of influenzal origin. The mother was of a neurotic temperament. About four weeks before, following a rather slight indisposition, probably influenzal, tendency of the eyes to turn in was noticed. The tonsils were removed a week later. Crossing of the eyes increased and became continuous. Two weeks later the child began to have distinct difficulty in speech and had several attacks of vomiting. About five days afterward difficulty in walking developed, accompanied by marked staggering. Swallowing was not involved at that time. When first seen he was pale, and there was a marked internal strabismus, double, but with greater involvement of the right eye. The pupils were normal; speech, very dysarthric, and there was slight power of phonation. The facial muscles were all in action, but the tongue did not protrude. There was some incoordination in arm movements, pendulum swaying when he sat erect, a reeling stagger when on his feet and inability to stand without support. The arm reflexes were negative; the patellar response, overactive and equal. There was no ankle clonus. The great toe sign was positive to all tests, including that which I have described. Distinct lethargy. No nuchal rigidity existed, and no Kernig sign. The next day swallowing was affected. Respiration became difficult; the heart, weak; the pulse, faint and fast, and, following a rapid failure of strength, the patient died that evening.

SIGNIFICANCE OF RESPONSE

The commonly accepted interpretation of a dorsal extension of the great toe on stimulation by any of the various tests is the presence of definite organic damage to the motor tracts or fibers at some level. And, undoubtedly, this is usually the condition; but not always. I have found the reaction present with the very earliest symptoms of acute cerebrospinal meningitis, on the second or third day in several cases, before organic destruction of motor neurons could have taken place; and I have seen the reaction diminish and entirely disappear with advancing recovery, no motor disability remaining. Barker's statement, therefore, that the positive toe sign does not appear until the second week is not correct.

SUCCESS OF NEW TEST

During the past two years, in which I have studied the occurrence of the pathologic great toe sign by the test here presented, it has been demonstrated in a fairly wide range of conditions of traumatic, inflammatory and degenerative type, including multiple sclerosis (frequently), spinal cord tumor, brain trauma, cerebral apoplexy, brain tumor (both cerebral and cerebellar), brain abscess, symptomatic epilepsy, syphilitic myelitis complicating tabes, spinal cord trauma, and lethargic encephalitis. It would therefore appear to be established as comparable to the Babinski test, only second to it in constancy of occurrence, and of identical significance and importance.

2. Crafts, L. M.: The Early Recognition of Multiple Sclerosis, *J. A. M. A.* 69: 1130 (Oct. 6) 1917.

ABSTRACT OF DISCUSSION

Dr. GEORGE A. MOLEIN, Denver: The last word has not been said about the reflexes as indicating destruction of the pyramidal tracts. We have all been impressed with the variety of stimuli applied to the leg which would produce an extensor response in cases of organic lesion of the projection tracts. Even the pricking of a pin, in such frank degenerative conditions, has produced extension of the toe, and the more severe the stimulus the greater the associated response. I think not only the dorsal foot reflex but the von Bechterew, the Babinski, the Gordon and the Oppenheim have a somewhat similar interpretation for most of us and must be accepted as indicative of a lesion, more or less destructive or inhibitory, of the tracts. In a recent case in which all the reflexes were lost, as well as all function below the region of the ninth dorsal segment and after a laminectomy, the recovery of partial function was evident. Most interesting was the reflex to which Marie has called attention, the reflex of inhibition, consisting of a voluntary flexion of the thigh on forced plantar flexion of the toe. This reflex seemed to be an elaboration of that which we have regarded as the more elaborate form of a Babinski reflex. I believe it is yet to be decided which of these reflexes is to be considered as indicative of partial lesion, and which a complete, of the spinal cord, and meanwhile hope that something more definite will be brought out besides the association of other reflexes on which we must all rely at the present time.

Clinical Notes, Suggestions, and New Instruments

DIAPHRAGMATIC HERNIA: REPORT OF CASE

JAMES G. WARE, M.D. (LOS ANGELES)

Lieutenant, M. C., U. S. Army; Chief of the Roentgen Service
CAMP KEARNEY, LINDA VISTA, CALIF.

History.—W. M. B., aged 29, cook with the American Expeditionary Forces, was wounded by fragments from a high explosive shell, Oct. 11, 1918, while serving with the second antiaircraft battalion. He states that immediately after the injury he experienced difficulty in breathing, and blood came from the mouth. He ran forward for several hundred feet before falling unconscious. Within an hour's time he was picked up by stretcher bearers, taken to an ambulance, and finally placed in a French hospital. Roentgenograms were made, and a large number of shell fragments were found scattered throughout the upper third of the thigh, together with a larger fragment in the left lung. Fourteen hours after he was wounded he was operated on, and these fragments were removed. At the same time a long incision was made over the left dorsal region; the eighth, ninth, and tenth ribs resected; and the shell fragment in the lung removed. The patient states that the surgeon informed him that the diaphragm was perforated in two places. He was confined to the hospital for two months.

For the first fifteen days following the operation he was practically unable to retain any nourishment. After that time, milk and other liquid diets were tolerated, and were followed by bully beef soup and cabbage, which the patient states, were not very appetizing. He substituted, therefore, articles of food that he could purchase.

Roentgenograms were again taken before he left France, and a diagnosis of pleural adhesions with contraction of the diaphragm was made. The medical treatment during his hospital care consisted principally of large doses of calomel, sodium bicarbonate, and castor oil.

The patient left France, Jan. 31, 1919, and was admitted to the base hospital at Camp Kearney, March 23. The following day he was sent to the roentgen-ray department with the request that roentgenograms be made of the left upper quadrant of the abdomen and the left chest.

The patient complained of inability to retain food of any solid variety, tolerating only liquids and the softer articles of diet. Food had to be administered cold; otherwise nausea and vomiting resulted. The patient complained of pressure symptoms and cardiac distress on exertion. Constipation was extreme.

Examination.—Nothing of interest could be found on routine examination, except some tenderness on palpation over the left upper quadrant of the abdomen.

plates now proved to be the stomach. In the standing position, the fluid level reached the margin of the tenth rib posteriorly, with the air bubble one-third the size of the barium shadow above that. Peristalsis was extremely slow, but after ten minutes' time the barium solution began to trickle through into a smaller sac, which was evidently the pyloric end of the stomach. The roentgen appearance was that of an hour-glass stomach (Fig. 2). The constriction of the stomach at this point was due to the contraction of

Fig. 1.—Dense mass filling the left side of the thoracic cavity up to level of fifth rib posteriorly.

Fig. 2.—Hour glass appearance of stomach with patient in standing position.

Fig. 3.—Plate made with patient in prone position. Barium fills out thoracic shadow seen in Figure 1.

Stereoscopic plates made of the thorax disclosed a dense mass filling the left side of the thoracic cavity up to the level of the fifth rib posteriorly (Fig. 1). Its upper surface was smooth and convex in outline, and resembled very much the picture often seen in severe cases of empyema in which the diaphragm is drawn up by adhesions. No fluid level could

the diaphragm around the stomach, but became effaced to some extent as the barium solution filled the lower sac. With the patient in the prone position, the barium solution completely rounded out the stomach, which now gave the appearance of being a thoracic organ, its upper border being on a level with the seventh rib posteriorly (Fig. 3). Seven hours

Fig. 4.—Six hour plate. Typical hour glass appearance. Constriction due to contraction of diaphragm.

Fig. 5.—Forty-eight hour plate showing position of splenic flexure at a point on a level with the intervertebral disk between eleventh and twelfth thoracic vertebrae.

Fig. 6.—Stomach three weeks after operation. Normal in shape and outline. Cap visualized.

be made out. The heart was crowded over to the right side, but was apparently normal in size when seen under the fluoroscope. From the history and the roentgen findings, a tentative diagnosis of diaphragmatic hernia was made, and the patient prepared for a gastro-intestinal examination.

He experienced considerable difficulty in taking the barium meal, but by drinking very slowly was able to ingest the full meal of 16 ounces. The obscure shadow seen on the first

later a barium residue was noted in the stomach, and here again was found the hour-glass appearance (Fig. 4).

Twenty-four and forty-eight hour plates showed practically no difference in the position of the barium column in the colon. The hepatic flexure was about normal in position, while the splenic flexure reached a point on a level with the intervertebral disk between the eleventh and twelfth thoracic vertebrae (Fig. 5).

Operation and Result.—An operation was performed by Major James F. Percy, chief of the surgical service, and Major T. E. Bailey. A median line incision was first made through the abdomen, but it was found impossible to reduce the stomach through this route. The stomach was adherent to the diaphragm and to surrounding structures. A second incision was made into the thorax, and the sixth and seventh ribs were resected. Two thirds of the stomach was found to be in the thoracic cavity, and was adherent to the pericardium. The adhesions were quickly separated, and the stomach reduced with considerable difficulty through a large opening in the posterior part of the diaphragm to which the stomach was adherent. The hole in the diaphragm was then closed, and the stomach now occupied a normal position in the abdomen. Forty-eight hours later the patient was smoking a cigaret and apparently comfortable.

Three weeks later the patient's condition was so improved that he was again sent to the roentgen-ray department. The stomach was apparently normal in position and outline. Peristalsis was regular and the pyloric cap visualized (Fig. 6.) The prognosis for a complete recovery is excellent.

PUNCTURED WOUND OF THE EXTERNAL ILLAC ARTERY WITH SUCCESSFUL TYING OF THE VESSEL

CHARLES F. DAVIDSON, M.D., EASTON, MD.

History.—L. S., aged 15, white, schoolboy, was thrown, Feb. 22, 1919, from a load of straw and fell on a three-prong pitchfork. His father, aged 40, was living and healthy. His mother died at the age of 35 of pulmonary tuberculosis. There were two brothers living, 6 and 10 years old, respectively, both healthy. One brother died in infancy. There were no sisters. He had not had any diseases except scarlet fever. He had always been healthy.

I reached the patient twenty minutes after the accident. He was entirely pulseless at the radial and temporal arteries. The heart sounds were indistinct. Respiration was 8; the skin was cold and covered with clammy sweat. The pupils were dilated and responded slowly to light. His mind was clear and he was thoroughly conscious. There was one lacerated wound over the pubic bones 3 inches long, through the skin to the bones. There was a punctured wound half way between the symphysis pubis and the anterior superior spine of the ilium. There was another punctured wound on the outside of the right anterior superior spine of the ilium through the skin to the bone and down along the outside of the bone 1 inch deep.

Preoperative Treatment.—The feet of the patient were elevated. Hot coffee enemas were given, one twelfth grain of morphin was given hypodermically, and 30 drops of aromatic spirit of ammonia in water were given every fifteen minutes for four doses. Absolute quiet was instituted. In two hours he said he felt better. The temporal pulse was 140; the radial pulse was wanting. He was then brought to the emergency hospital on the cot on which he was found and one-twelfth grain of morphin and $\frac{1}{150}$ grain of atropin were given hypodermically. The patient was carried to the operating room half an hour later. Anesthesia was begun at 3:10 p. m. The temporal pulse was 140. The operative area was washed with alcohol followed by ether and painted with iodine.

Operation.—This was begun at 3:25 p. m. The temporal pulse was 110. The operation was completed at 4:15 p. m. The radial pulse was 140. The lacerated wound over the pubic bone was sutured. The punctured wound on the outside of the pelvis was opened at the lower end, and a gauze through and through drain was put in. Incision was made at the edge of the right rectus. As soon as the rectus muscle was pushed aside, it was seen that black, clotted blood had infiltrated the peritoneum and all the tissues. Black, clotted blood was between the serous and the muscular coats of the bladder and the intestine, particularly the cecum, which was as black as the bladder. There was free clotted blood at the lower point of the right kidney. At least a pint of

clots was removed from this point. There was no free blood within the peritoneal cavity. No perforation in the intestine could be found. After the intestine was pushed aside, there was a gush of bright red blood into the field. I seized the right common iliac artery with the thumb and forefinger of the left hand. The anesthetist said: "One more like that and he will be dead." The incision was enlarged. The field was packed off and the external iliac artery was brought into view. I lessened the pressure on the common iliac and bright red blood rushed from a little hole not larger than the lead in an ordinary lead pencil in the front and about the middle of the external iliac. I tightened my grasp on the common iliac. All the blood was sponged out and the hole was plainly visible in the external iliac. Hemostatic forceps were put on the external iliac artery, one on each side of the hole, and the grasp on the common iliac was released. The hemorrhage was controlled. It was just 4 o'clock when the clamps were applied. The clamp on the cardiac side moved on each pulsation of the heart. A silk ligature was put around the artery on the cardiac side of the clamp and one on the distal side of the other clamp. A cigaret drain was put at the lower end of the right kidney, one down in the pelvis behind the bladder, and one under the cecum. These were brought out of the abdominal incision and the wounds closed to the drains and the two hemostatic forceps that were left in situ. It was impossible to close the peritoneum because it was so infiltrated with blood as to make it so friable that the stitches would not hold. The aponeuroses were drawn together with twenty-day chromicized No. 3 catgut and the skin was sutured with silkworm gut. The patient left the operating table at 4:15. During the operation Dr. W. T. Hammond, with the assistance of a nurse, gave by infusion 1,000 c.c. of physiologic sodium chlorid solution and constantly administered oxygen with ether. He gave the anesthetic and conducted that part of the operation that kept the patient alive during the operating work.

Clinical Course.—The patient was sent to his room with a radial pulse of 146 and a respiration of 30. An immunizing dose of tetanus antitoxin was given as soon as he became conscious after the anesthesia. The right leg became purple and enlarged in size. Pulsations were first felt in the posterior tibial artery at 6:10, two hours and ten minutes after the external iliac was fastened with the hemostatic forceps. The right leg immediately commenced to become normal and in a few hours was the same color and the same size as before the accident. When the patient was first sent to his room, his head was lowered and proctoclysis with physiologic sodium chlorid solution by the drip method was begun. After regaining consciousness the patient complained of great thirst and was given water. The next day he took and retained broths, soft eggs and milk. The hemostatic forceps were removed on the fourth day and the drains were started on the fifth day and were entirely removed on the eighth day, to be replaced by smaller ones. As soon as his condition allowed it he was placed in Fowler's position. There was very little draining the first three days, but profuse draining after that. Whenever his temperature and pulse would go high, a Kelly clamp passed in the wound would drop down behind the bladder and a profuse discharge of pus would follow the withdrawal of the clamp. The patient made an uneventful recovery and left the hospital, April 5, 1919, still draining but with not retention enough to cause any rise of temperature.

The patient reported to my office May 17 and again June 2, walking well. He said he was all right and felt fine. The abdominal wound was entirely healed at the time of the visit, May 17.

COMMENT

My only other experience in tying the external iliac artery was when I was in von Bergmann's clinic. I saw him tie the external iliac for a traumatic aneurysm of the femoral caused by sheep-shears puncturing this vessel. In this case it was one hour and ten minutes before collateral circulation was established, the difference being due to the fact that his patient was in perfect health and my patient was in collapse from hemorrhage.

THE RENAL THRESHOLD FOR BLOOD SUGAR

The widespread application of quantitative blood sugar tests in the study of disease promises to be helpful not only in diagnosis but also in the therapeutic management of patients. It is impossible to make complete reference here to the numerous meritorious researches on blood sugar. Nevertheless, we may justly point with a certain amount of pride to the patent fact that alike in the devising of experimental methods and in the refined study of the new problems of carbohydrate metabolism, American investigations in the laboratories and clinics have been second to none. Science, it is true, knows no boundaries of race or nationality; but the time has come when charges of practical materialism shall no longer overshadow the just deserts of American research in medicine.

As an outcome of the newer work it has seemingly become important to look on hyperglycemia, or an abnormally high level of blood sugar, as competing in significance with glycosuria, or glycosuria, as it has been more recently designated.¹ Heretofore, emphasis has for the most part been placed solely on the content of sugar in the urine. This was inevitable so long as practicable methods of estimating the level of glucose in the blood were not yet available. Today, rapid procedures of sugar analysis on readily obtainable small samples of blood have altered the situation. By such tests it has become evident that a considerable elevation of the blood sugar level may occur under certain circumstances without evidence of the fact in the urine. The problem of the renal threshold for sugar elimination is thus raised. If the average normal blood sugar value is placed at 0.11 per cent., with a range of from 0.07 to 0.14 per cent. of glucose, the normal threshold will probably be not far removed from 0.17 or 0.18 per cent. Only when the sugar concentration in the blood exceeds this figure does the carbohydrate ordinarily escape into the urine in appreciable amounts.

The renal threshold may become decidedly higher in such diseases as diabetes and nephritis. Basing their conclusions on observations in the Hahnemann Hospital at Rochester, N. Y., Williams and Humphreys² assert that the threshold in diabetes tends to rise with the prolonged duration and the increasing severity of the disease. According to them, younger diabetics as a rule have low or normal thresholds. The threshold rises with advancing years. When the diabetes is mild or quiescent, the point at which the kidneys eliminate sugar is stationary; but when the disease becomes progressive, the threshold tends to rise. Indeed, before death the blood sugar renal threshold may reach great heights with little or no sugar appearing in the urine. A rising renal threshold for sugar in the face of careful dietary treatment is a serious prognostic sign. A high renal threshold for sugar in mild diabetes under proper dietary regulations usually indicates some complication, as arterial hypertension.

An important practical problem arises out of these recently discovered facts regarding the renal threshold for sugar. What is the proper index of tolerance for carbohydrate? Shall the intake of this group of nutrients be regulated to prevent glycosuria or to reduce the blood sugar level to a lower threshold value? Let us bear in mind that glycosuria is not a necessary accompaniment of decreased tolerance which may be measured in diverse ways.³ Mosenthal⁴ and his collaborators at the Johns Hopkins Hospital have suggested that a high blood sugar level in diabetes may be a protective mechanism, conserving the carbohydrate somewhat for the uses of the organism. Williams and Humphreys rejoin in the belief that persistent high blood sugar levels promote exhaustion and rapid decline of function, and that the high threshold is merely a safety measure. In severe diabetes, in which extremely low diets are necessary to maintain life, the high threshold is essential to take care of the seriously impaired carbohydrate metabolism. In the treatment of diabetes, they add, it is desirable to maintain the blood sugar level as nearly normal as possible, even though severe restrictions in diet may be necessary for this purpose, and notwithstanding the fact that the high threshold will permit of a much more liberal diet without the appearance of sugar in the urine.

We are not prepared to take a final stand in this issue. On the outcome must depend the proper plan of dietotherapy in diabetes. From the one standpoint,

food would be permissible just short of the amount that induces glycosuria; from the other, the indication for control would be found in the blood sugar level rather than in urine tests. A further feature of practical interest has been pointed out anew by Williams and Humphreys. In severer cases of nephritis, patients may excrete small quantities of sugar in the urine, frequently giving rise to the misapprehension that true diabetes exists. In such cases, they remark, the blood sugar level is inappreciably influenced by carbohydrate restriction, and these patients should not be subjected to the discomfort of rigorous diabetic diet.

ANTISCORBUTICS: I

Ever since Holst and Fröhlich¹ asserted, in 1912, that the antiscorbutic property of certain fresh vegetables and fruits may be to a large extent lost when they are subjected to a high temperature or are dried, students of nutrition have been more alert to the possible effects of culinary processes on some of the less understood properties of foods. Although, as has already been discussed in these columns, McCollum and his colleagues have assumed that scurvy is a disease related to intestinal putrefaction and the retention of feces, the concordant opinion of other recent investigators, notably Givens, Hart, Hess, Mendel, Steenbock and their co-workers in this country, and Chick, Harden and their collaborators in England, has substantiated the earlier view that the disease is the result of a deficiency of some nutritive factor in the diet. From this standpoint we may speak of the lack of an antiscorbutic vitamin, just as the lack of an anti-neuritic vitamin is postulated in the genesis of polyneuritis.²

The lack of knowledge of the distribution of antiscorbutic vitamins has been accentuated by the needs of infant feeding. The use of cow's milk pasteurized at a temperature as low as 63 C. (145.4 F.) for thirty minutes has led in the course of several months to milk outbreaks of infantile scurvy,³ thus indicating the poverty of heated milks in the antiscorbutic vitamin. Only recently Hart, Steenbock and Smith have demonstrated at the University of Wisconsin that milk sterilized at 120 C. for ten minutes, commercial unsweetened condensed milk, and the commercial milk powder examined had lost their antiscorbutic properties when used in quantities equivalent to an amount of raw milk which would prevent scurvy in guinea-pigs on a diet of rolled oats and dried hay. From such

citations it becomes evident why investigators of infant feeding have sought suitable sources of antiscorbutics and why producers of food preparations are concerned with the retention of native antiscorbutic potency so far as this is possible. Recent writers⁴ have sanely summarized the situation by saying that either the results with guinea-pigs on experimental scurvy should not be translated to infantile scurvy, or we should follow the wiser course of using some antiscorbutic in conjunction with the exclusive use in infant feeding of such heated milk products as have been described.

Thanks to the labors of a number of investigators both here and abroad, the pediatrician is no longer limited to the conventional orange juice in his efforts to avert scurvy in infants. Reference has been made in THE JOURNAL to some of the novelties, such as the raw juice of the swede and the tomato, which are also available for human nutrition. Although the antiscorbutic value of fruit juices was recognized three hundred years ago, Alice Henderson Smith⁵ of the Lister Institute in London has upset the traditional faith in lime juice, as the result of her historical studies. It appears that the juice used with good effect in the olden days was in reality obtained from lemons and sweet limes, not from the West Indian sour limes. With the change to the sour limes has come a failure in antiscorbutic potency that was difficult to understand until it was demonstrated recently by experimental tests on animals that the sour lime of the West Indies (*Citrus medica-acida*) happens to have only one quarter of the antiscorbutic value of the lemon (*Citrus medica-limonum*). Lemon juice is easily available for the treatment of infantile scurvy. Harden and Zilva⁶ have further demonstrated that after removal of the free citric acid and other acids from lemon juice, the residue also retains its antiscorbutic activity; and in collaboration with Still⁷ these investigators have, for the first time, clinically employed with success this antiscorbutic factor separated from the greater part of the inactive components in combination with which it occurs. The vitamin-containing product could be administered in large dosage after the refinement and the exclusion of extraneous substances. In fact, the lemon product was given in concentration at least double—in one case seven times—as strong as the form in which it occurs naturally in the food-stuff (lemon) from which it was obtained. The treatment was thus, so to speak, "intensive," reminding one of the seemingly potent therapeutic procedure of Hess, who introduced orange juice directly into the circulation of scorbutic infants.

There are indications that the potent fruit juices can be suitably preserved for clinical use. This is a matter of no little consequence in conserving products that do not come into the market with uniform frequency and at reasonable prices throughout the year. Harden and Robison⁷ have reported from London that the antiscorbutic principle in orange juice is not volatilized when the juice is distilled at 40 C. under reduced pressure. By evaporation of orange juice at 40 C. under reduced pressure, it is possible to obtain a solid residue which possesses in a very high degree the antiscorbutic value of the fresh juice. This value is not appreciably diminished when the substance is kept in a dry atmosphere at room temperature during six months. The prolonged heating to which fruit juices are subjected in the usual processes for the manufacture of jams and jellies renders it unlikely that these would ever possess any considerable antiscorbutic value. Nevertheless, Harden and Robison have found that by the use of the newer extremely rapid commercial processes of concentration without the application of high temperatures, fruit jellies can be prepared (from the apple, for example) which are by no means devoid of antiscorbutic potency, though this is of a different order from that characteristic of the orange and lemon. Surely there can no longer be any excuse for the failure to avert infantile scurvy, even when fresh, unheated milk is not available.

THE PHYSICAL EXAMINATION OF THE FIRST MILLION DRAFT RECRUITS

A recent bulletin from the Surgeon-General's Office discusses the methods followed and the results secured in the physical examination of the first million draft recruits. The initial selected draft of 1917 was the first opportunity that this country had had in half a century to make a census of the physical constitution of its people. It is doubtful whether any physical survey in the history of the country is comparable to it. Approximately 10,000,000 men from 21 to 30 years of age were registered. Of these, 2,510,000 were examined physically by the local draft boards prior to Dec. 15, 1917. Of this number, 730,000, or approximately 29 per cent., were rejected on physical grounds. Between Dec. 15, 1917, and Sept. 11, 1918, 3,208,446 men were examined by local draft boards. Out of these two groups, approximately a million men were sent to the mobilization camps and there reexamined. The results of this second examination of the million draft recruits are recorded in this report. The Surgeon-General's Office announces that a report will be published later, containing all the information concerning the men accepted and sent to camp, those rejected by the local boards and those discharged from the army for disability.

This material naturally involves an enormous amount of detail. Some general conclusions, however, can be made. While reports from the different camps naturally varied considerably on account of the variation in ideals of the physical examining boards, it is possible to show that the incidence of particular defects and diseases varied in different sections of the country; for instance, these figures show strikingly the large prevalence of goiter in the region of the Great Lakes and the Northwest. Another striking fact is the overwhelming predominance of flatfoot as a physical defect. This condition was found in the ratio of 177.45 per thousand, or nearly eight times as frequently as any other defect. Twenty-two per cent., or more than one fifth of the rejections, were caused by a mechanical defect such as flatfoot, defects in the bones and joints, hernia, etc.; 15 per cent. of rejections were on account of imperfections of the sense organs; 13 per cent. were due to defects in the cardiovascular system; 12 per cent. to nervous and mental troubles; 10 per cent. were rejected on account of communicable diseases, almost entirely tuberculosis and venereal diseases; 8.5 per cent. were rejected because of developmental defects, and 6 per cent. on account of skin diseases and imperfection of the teeth. The comparison between men coming from rural and urban communities is also interesting. The local boards rejected from certain selected urban districts 21.68 per cent., and from rural districts 16.89 per cent. The total number of defects found in urban recruits was 38.3 in each hundred, while the defects among rural recruits were 33.3 per hundred. While flatfoot is the greatest defect noted, the amount of flatfoot reported from the Southern states is markedly less than that from the Northern states. Probably the mildness of the climate and the general custom of negroes and boys—especially among the rural classes—going barefoot is responsible for the better development of the feet and consequently for the smaller percentage of flatfoot in the South. Men from the large cities show much greater proportion of hernia than do men from the rural districts. Venereal diseases are found predominant in the Southern states, while the Northwest has a much lower percentage than any other section of the country. Defective vision is found more commonly among recruits from New England and New York City than from the Central states. Trachoma is more common among the recruits from Kentucky, Indiana, Illinois and Missouri than from the other states. Varicose veins are especially common in Minnesota and Wisconsin and the mountainous regions of the extreme Northwest. Underweight was found more commonly in the Western and Northwestern states than elsewhere. Defective physical development was found in the New England states to an unusual degree. Men from the cities showed 30 per cent. more defective vision than men from the country. Otitis media is about 60 per cent. more common in the cities than in the country, while

⁷ Harden, A., and Robison, R.: The Antiscorbutic Properties of Concentrated Fruit Juices, *J. Roy. Army Med. Corps*, January, 1919.

mitral insufficiency is 60 per cent. more common in the country than in the city. Chronic alcoholism and drug addiction are much more common in the city than in the country. Defects of vision are in direct ratio to the size of the cities. Valvular heart disease is, speaking roughly, inversely proportionate to the density of the population.

The report contains more than 500 pages of tables, charts and plates, giving all the details for the million men, classified by states, by defects and graphically. By the statistical method it gives a new insight into the physical status of our young men.

Current Comment

INCIDENCE OF CARCINOMA OF TONGUE AND LIP FIFTY YEARS HENCE

In his recent Bradshaw lecture, Mr. D'Arcy Power¹ reviewed the salient facts regarding the history of cancer of the tongue and ventured the assertion that, fifty years hence, we shall see an enormous increase in the incidence of this disease, and that it will become relatively as common among women as among men. The grounds for this assertion are rather interesting. No one is bold enough to claim knowledge of the basic cause of cancer; nevertheless, we are all aware that cancer is much more likely to appear under certain conditions than others, and that by the use of certain agents, as, for instance, the roentgen ray, we can induce cancer almost at will. To a limited extent, therefore, one predisposing and exciting cause of cancer has been discovered, in the form of appropriate types of chronic irritation. Cancer of the tongue among lower animals is rare, there being only about five cases on record. Power presents evidence to show that, up to the time when syphilis, the use of tobacco, and the excessive, widespread abuse of alcohol were introduced, the incidence of carcinoma of the tongue in the human family did not exceed that at present found among lower animals. Carious teeth are probably without great significance. Examination of a multitude of skulls reveals the incidence of caries of the teeth among the ancient Romans in Britain to have been on a par with that among the present inhabitants of London; yet cancer of the tongue is a disease of modern life. When syphilis became rampant, lesions of the mouth, of course, greatly increased in frequency; yet cancer remained uncommon. It was only when the habit of smoking tobacco became firmly established that the incidence of buccal cancer showed a sharp increase. The frequency with which cancer arises from syphilitic scars in the mouth has been frequently commented on. Without discussing further the evidence produced, it may be stated that, from the historical standpoint, syphilis appears to be the great predisposing cause of buccal cancer, and chronic irritation, particularly that due to smoking, the great exciting cause. In spite of the propaganda against

venereal disease, there is as yet no reason to suppose that the incidence of syphilis will show any substantial decline during the next half century, while the smoking habit is yearly becoming more widespread, especially among women. Cancer of the tongue and lip has increased threefold in the past thirty years. In view of the facts as stated, the incidence of buccal cancer fifty years hence becomes, indeed, a matter of interesting speculation.

JACOBI AS A REVOLUTIONIST

As we stated last week, Abraham Jacobi was one of the well known "forty-eighters." The story of Carl Schurz as a revolutionist is familiar to many, while that of Jacobi, his dearest friend, has yet to be told in all its details. Schurz relates that in 1850 he first met Jacobi, then a student of medicine at Bonn and a "zealous democrat," and adds that later in the year Jacobi was "on his way to Schleswig-Holstein, to offer his services as a physician to our struggling brethren." For his activities in the cause of the revolution, Jacobi was accused of high treason—at the age of 21—and was confined in prisons at Cologne and Minden for about two years. On his release in 1853 he went to England, for it was reported that new charges were to be made against him; but he stayed there only a short time, and on the advice of Schurz moved to America, where he became a citizen as soon as possible. Sir William Osler once praised Dr. Jacobi for having refrained from writing for publication during the seven years following his graduation from the University of Bonn. Jacobi's comment on this was:

He did not know that in nearly two years of those seven I never saw a square inch of paper or more than an infinitely small pencil which I concealed in my hair. When I saw the light again the French Republic had been destroyed nearly two years and the world had changed its shape.

THE CARE OF PUBLIC WATER SUPPLIES

It is not enough for a city to introduce a water supply from a pure source, or to install a good filtration plant for a slightly polluted water or to undertake to purify a contaminated water by chlorine treatment, and stop at that. Any one of these methods may be justified by local conditions, but unless the surroundings of the pure water supply be jealously guarded at all times, and unless the efficacy of purification methods is frequently tested and controlled, there is danger that the supply may come to grief through an "accident" which a not too superhuman sagacity might have prevented. In the case of a water supply, eternal vigilance is the price of safety. Two typhoid epidemics recently reported¹ may adorn the tale. In Xenia, Ohio, there were only two typhoid cases in 1917 and none in 1918 up to August 27. From that date, however, seventy-seven cases were reported. On investigation it seemed clear that the common source of the infection was the water supply, and it was soon discovered that, although a bleach solution had been carefully added to the water, an inferior bleaching powder

1. Power, D'Arcy: On Cancer of the Tongue; The Bradshaw Lecture, 1918, *Brit. Jour. Surg.*, 6: 336 (Jan.) 1919.

1. J. of the Am. Water Works Assn., June, 1919.

(though guaranteed to be of proper strength) had been used and that the solution was only about one fifth as effective as it should have been. The regular application of simple tests might have prevented the whole trouble. In Moline, Ill., also an explosive attack of typhoid occurred in 1918. Although the precise method of water contamination was perhaps less clear in this case than at Xenia, the investigation brought to light the fact that various contaminations of the pure water supply with a polluted source existed, and that through some carelessness the contaminated water had been allowed to mix with the pure water supply. "The chemist had opened the by-pass about 5 p. m. on June 21 and left it open until about 2 p. m. on June 22. During this period one of the sedimentation tanks had been cleaned, cutting the sedimentation period in two, which permitted water even poorer than usual to enter the clear well. A study of the records showed that the chlorin was on only a part of the time the water was being by-passed. Later information was secured from a diary kept by the chemist that the by-pass was also open during a part of June 19. During portions of this period little or no chlorin was being added. There is no doubt but that the typhoid outbreak in July resulted from the opening of the by-pass on the dates mentioned." One conclusion drawn from this "incident" was that "in a filter plant treating a polluted stream, water by-passes should under no conditions be tolerated. This means that the plant must be of ample capacity to supply sufficient filtered water at all times." With this conclusion there will be general agreement.

THE CAUSE OF WAR EDEMA

Early in the course of the war, when the food supply of the Central Empires began to be jeopardized, reports of unusual maladies became current in many of the countries affected. Among the forms of illness apparently associated with dietary shortcomings was a peculiar type of edema which came to be known as "war dropsy" or "war edema." Several hypotheses have been advanced in explanation of its occurrence. At first war edema was charged to undernutrition attributable to short rations. Presently, however, the disease seemed to be attendant on the lack of certain essential dietary components rather than a diminished intake of food as such. The increasing restrictions in the variety of food products consumed tended to lead to "one-sided diets." The suggestion was therefore soon ventured that lack of certain vitamins, notably the fat-soluble food accessory occurring in cream, butter, beef fat, fish oils and egg yolk, as well as green vegetables, was responsible for the appearance of the edema. Recent experimental studies by Kolman¹ at the Physiological Laboratory of the University of Chicago suggest, however, that "war dropsy" may be due to an insufficiency of protein in the diet, rather than to a vitamin deficiency. Thus, animals placed on rations low in protein, the latter being supplied

by carrots alone, in numerous instances developed marked edema which manifested itself in various ways, sometimes with fluid in the pleural and peritoneal cavities, and sometimes with fluid collected subcutaneously, especially over the chest and about the forelegs. Weakness always occurred and usually loss of weight, aside from the gain due to accumulation of fluid in the tissues. Enrichment of the diet in protein averted such abnormalities.

BILL FOR A NATIONAL DEPARTMENT OF HEALTH

Elsewhere¹ appears an abstract of a bill creating a national department of public health. This bill, introduced by Hon. Joseph I. France, United States Senator from Maryland and Chairman of the Senate Committee on Public Health and National Quarantine, is one of the most comprehensive measures on this subject that has been prepared. Three bills creating a national department of health are now before Congress, each of them drafted on broader lines than those of previous years. The need of an adequate and efficient national department of health is more apparent today than ever before. Legislators, physicians and laymen are more than ever agreed as to its desirability. Exactly what form it will take remains to be seen; but if all those interested in better national health organization will cooperate, constructive legislation in this field will soon become a reality.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending July 18, there were 11,755 officers in the Medical Corps, a decrease of 633 from the previous week. The Medical Reserve Corps contained 2,949 officers. The total number of physicians discharged since the beginning of the war is 21,232.
